

ABOV SEMICONDUCTOR Co. Ltd.
8-BIT SINGLE-CHIP MICROCONTROLLERS

MC80F7708

User's Manual (Ver. 1.21)

REVISION HISTORY

VERSION 1.21 (December 03, 2012) This Book

ABOV logo is renewed on this book.

Single and Gang writer are updated in "1.3 Development Tools" on page 3.

VERSION 1.2 (March 17, 2009)

Modify Timer capture mode description in "Figure12-10 / Figure 12-11/Figure 12-15 8bit/16bit capture mode".

VERSION 1.1 (February 2, 2009)

Modify BIRR description in "Figure24-1 Block Diagram of BIR (Built-In Reset)".

Modify Port structures(R43, R42 ,R20/AN0~R23/AN3, R24/AN4~R25/AN5)

VERSION 1.0 (April 1, 2008)

Corrected PSW(NVGBHIZC) for "INC A" instruction from N----ZC to N----Z- at " Arithmetic / Logic Operation" on page iv.

VERSION 0.7 (OCT 17, 2007)

Modify CTR(Contrast Controller Level Selection) in Figure 18-3 LCD Bias Control

VERSION 0.6 (MAY 02, 2007)

Modify FLASH memory endurance : 1000 cycles to 100 cycles (page 1).

VERSION 0.5 (APR 09, 2007)

Remove P-MOS protection diode of LCD SEG or COM pin(R50~R57, R60~R67, R70~ R77) in page 13.

Add R7, R4, R4IO, R4OD and R4PU registers to "Table 8-1 Control Registers". (page 27, 28)

Fix reset value of R4OD and R4PU from 00-0--0-B to -000000-B and 0000000-B. (page 37)

Change R6IO(0CDh) to R7IO(0B4h) and add R74 ~ R75 in R7 port describing Figure(page 38)

Version 1.21

MC80F7708

CMOS SINGLE-CHIP 8-BIT MICROCONTROLLER WITH LCD CONTROLLER/DRIVER

1. OVERVIEW

1.1 Description

The MC80F7708 are an advanced CMOS 8-bit microcontroller with 8K bytes of FLASH ROM(MTP). This device is one of the MC800 family and a powerful microcontroller which provides a high flexibility and cost effective solution to many LCD applications. The MC80F7708 provide the following standard features: 8K bytes of FLASH ROM, 256 bytes of RAM, 20 bytes of segment LCD display RAM, 8/16-bit timer/counter, 10-bit A/D converter, 7-bit watch dog timer, 21-bit watch timer with 7-bit auto reload counter, 8-bit UART, on-chip oscillator and clock circuitry. In addition, this device supports power saving modes to reduce power consumption. So the MC80F7708 is the best controller solution in system which uses chartered LCD display and ADC.

Device name	Memory (Bytes)		ADC	PWM	UART	I/O	LCD	Operating Voltage	Package
	ROM	RAM							
MC80F7708Q	8K	256	6ch.	1ch.	1ch.	42	16SEG x 8COM (20SEG x 4COM)	2.2 ~ 5.5V	44MQFP
MC80F7708K	8K	256	4ch.	1ch.	1ch.	40	16SEG x 8COM (20SEG x 4COM)	2.2 ~ 5.5V	42SDIP

1.2 Features

- **8K Bytes On-chip FLASH ROM (MTP)**
- **FLASH Memory**
 - Endurance : 100 cycles
 - Data Retention : 10 years
- **256 Bytes On-chip Data RAM**
- **20 bytes Display RAM**
- **Instruction Cycle Time:**
 - 333ns at 12MHz (2 cycle NOP instruction)
- **LCD display/controller**
 - 1/4 Duty Mode (20Seg x 4Com, 1/3 Bias)
 - 1/8 Duty Mode (16Seg x 8Com, 1/4 Bias)
- **Four 8-bit Timer/Counter**
(They can be used as two 16-bit Timer/Counter)
- **One 7-bit Watch Dog Timer**
- **One 21-bit Watch Timer**
 - 1 minute interrupt available
- **One 8-bit Basic Interval Timer**
- **One 6-bit Buzzer Driving Port**
- **Dual Clock Operation**
 - Main Clock : 400kHz ~ 12MHz
 - Sub Clock : 32.768kHz
- **Main Clock Oscillation**
 - Crystal
 - Ceramic Resonator
 - Internal Oscillation : 8MHz/4MHz/2MHz
- **Operating Temperature : -40~85 °C**
- **Built-in Noise Immunity Circuit**
 - Noise Filter
 - BIR (Built-in Reset)
- **Power Down Mode**
 - Main Clock : STOP, SLEEP mode
- **400kHz to 12MHz Wide Operating Frequency**
- **On-Chip POR (Power On Reset)**

- Internal Resistor for LCD Bias
- 42/40 Programmable I/O Pins

MC80F7708Q	I/O: 17 I : 1 I/O with SEG/COM:24
MC80F7708K	I/O: 15 I : 1 I/O with SEG/COM:24

- 6/4-channel 10-bit On-chip A/D Converter

MC80F7708Q	6-channel ADC
MC80F7708K	4-channel ADC

- One 10-bit High Speed PWM Output

- 14 Interrupt sources
 - External Interrupt : 4
 - Timer : 4
 - UART : 2
 - ADC, WDT, WT, BIT
- One Universal Asynchronous Receiver/Transmitter (UART) at FLASH MCU
- 2.2V to 5.5V Wide Operating Voltage Range
- 44MQFP, 42SDIP Package Types
 - Available Pb free package

MC80F7708Q	44MQFP
MC80F7708K	42SDIP

1.3 Development Tools

The MC80F7708 are supported by a full-featured macro assembler, an in-circuit emulator CHOICE-Dr.TM and OTP programmers. There are two different type of programmers such as single type and gang type. For mode detail, Macro assembler operates under the MS-Windows 95 and upversioned Windows OS. And HMS800C compiler only operates under the MS-Windows 2000 and upversioned Windows OS.

Please contact sales part of ABOV semiconductor.

Software	<ul style="list-style-type: none"> - MS-Windows based assembler - MS-Windows based Debugger - MC800 C compiler
Hardware (Emulator)	<ul style="list-style-type: none"> - CHOICE-Dr. - CHOICE-Dr. EVA80F77 B/D Rev1.0

1.4 Ordering Information

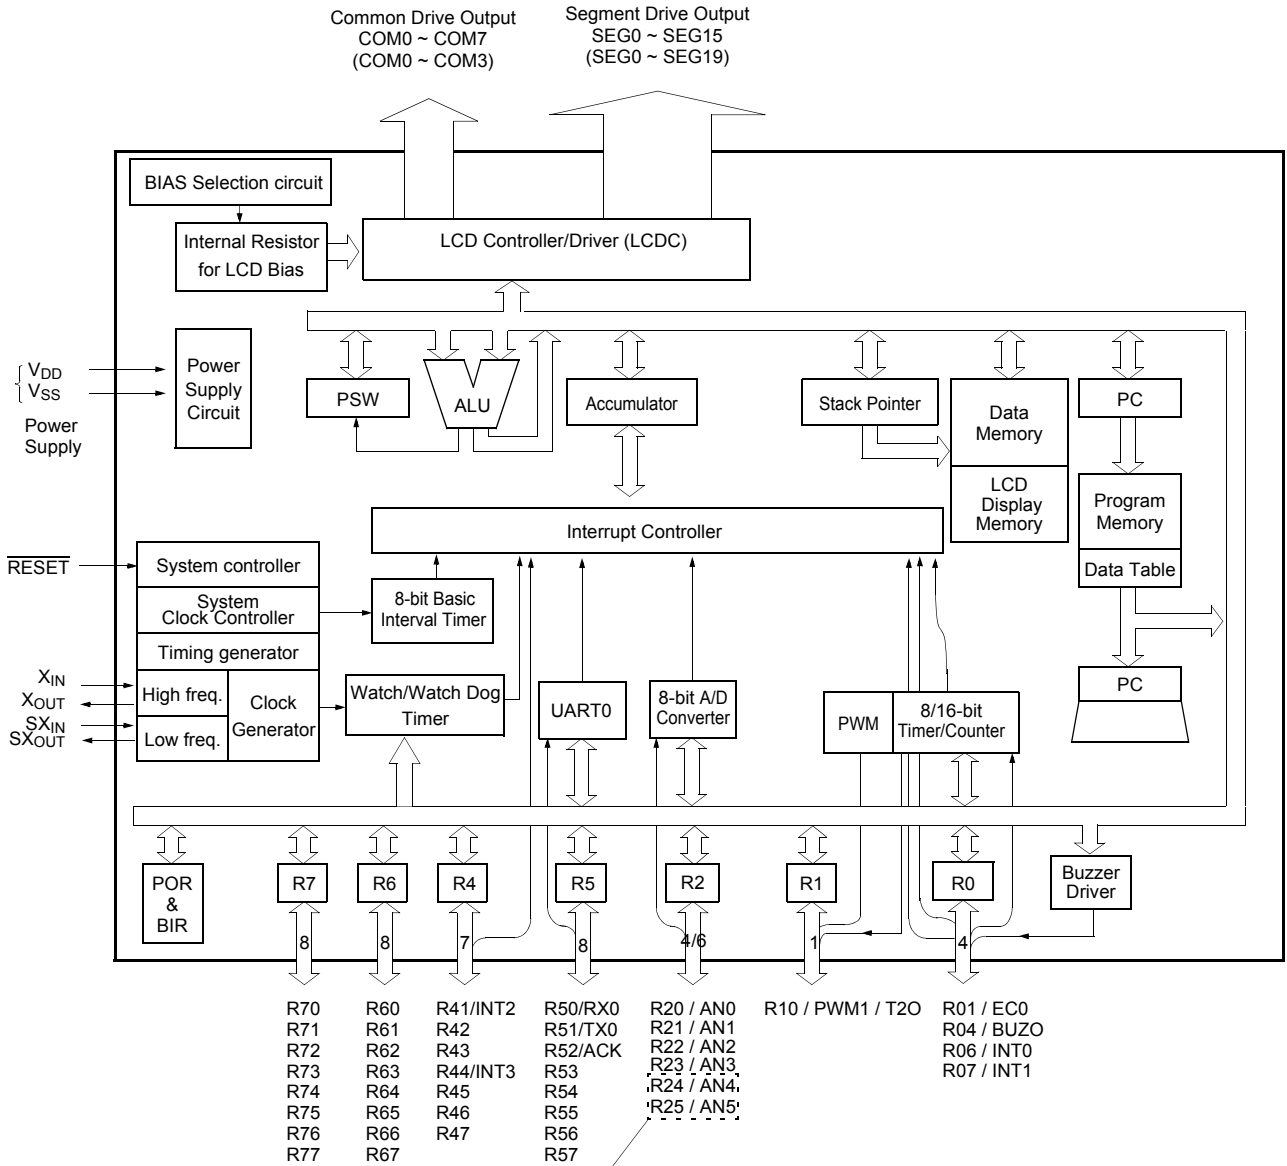

Device name	ROM Size	RAM size	Package
MC80F7708Q	8K bytes FLASH	256 bytes	44MQFP
MC80F7708K	8K bytes FLASH	256 bytes	42SDIP

- Pb free package;

The “P” suffix will be added at original part number.

For example; MC80F7708Q(Normal package), MC80F7708Q P(Pb free package)

2. BLOCK DIAGRAM

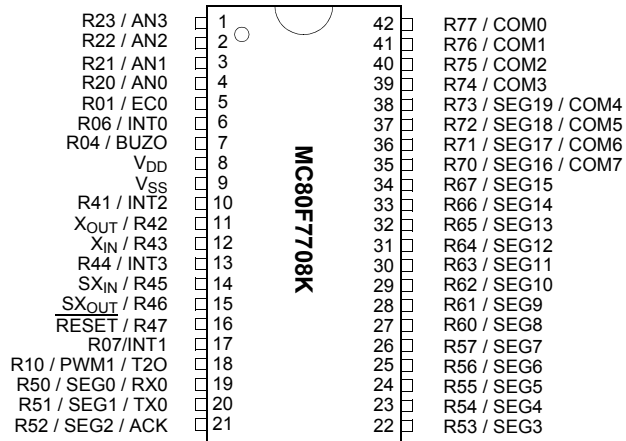

*R24/AN3 and R25/AN5 are not supported in MC80F7708K(42pin).
 MC80F7708Q : R20/AN0 ~ R25/AN5
 MC80F7708K : R20/AN0 ~ R23/AN3

3. PIN ASSIGNMENT

**44MQFP
(Top View)**

**42SDIP
(Top View)**

*R24/AN3 and R25/AN5 are not supported in MC80F7708K(42pin).

4. PACKAGE DIAGRAM

5. PIN FUNCTION

V_{DD}: Supply Voltage.

V_{SS}: Circuit ground.

RESET: Reset the MCU Reset.

X_{IN}: Input to the inverting oscillator amplifier and input to the internal main clock operating circuit.

X_{OUT}: Output from the inverting oscillator amplifier.

SX_{IN}: Input to the internal sub system clock operating circuit.

SX_{OUT}: Output from the inverting subsystem oscillator amplifier.

SEG0~SEG19: Segment signal output pins for the LCD display. See "18. LCD DRIVER" on page 76 for details. Also SEG0~SEG19 are shared with normal I/O ports and SEG16~19 are multiplexed with COM7~COM4.

COM0~COM7: Common signal output pins for the LCD display. See "18. LCD DRIVER" on page 76 for details. Also COM0~SEG7 are shared with normal I/O ports and COM4~COM7 are multiplexed with SEG19~SEG16.

COM4~COM7 and SEG19~SEG16 are selected by LCDD0 of the LCR register.

LCDD0	COM4~COM7 / SEG19~SEG16
0	COM4 ~ COM7
1	SEG19 ~ SEG16

R01, R04, R06, R07: R0 is a 4-bit CMOS bidirectional I/O port. R0 pins 1 or 0 written to the Port Direction Register can be used as outputs or inputs. Also, pull-up resistors and open-drain outputs can be assigned by software.

In addition, R0 serves the functions of the various following special features.

Port pin	Alternate function
R01	EC0 (Timer 0 Event Count Input)
R04	BUZO (Buzzer Output)
R06	INT0 (External Interrupt 0 Request Input)
R07	INT1 (External Interrupt 1 Request input)

R10 : R1 is an 1-bit CMOS bidirectional I/O port. R1 pins 1 or 0 written to the Port Direction Register can be used as outputs or inputs or schmitt trigger inputs. Also, pull-up resistors and open-drain outputs can be assigned by software.

In addition, R1 serves the function of the following special feature.

Port pin	Alternate function
R10	PWM1/T2O (Timer3 PWM Output / Timer2 Output)

R20~R25: R2 is a 4/6-bit CMOS bidirectional I/O port. Each pins 1 or 0 written to the Port Direction Register can be used as outputs or inputs. Also, pull-up resistors and open-drain outputs can be assigned by software.

In addition, R2 serves the functions of the various following special features.

Port pin	Alternate function
R20	AN0 (Analog Input Port0)
R21	AN1 (Analog Input Port1)
R22	AN2 (Analog Input Port2)
R23	AN3 (Analog Input Port3)
R24	AN4 (Analog Input Port4)
R25	AN5 (Analog Input Port5)

Note: R24/AN3 and R25/AN5 are not supported in MC80F7708K(42pin).

R41~R47: R4 is a 7-bit CMOS bidirectional I/O port. Each pins 1 or 0 written to the Port Direction Register can be used as outputs or inputs. Also, pull-up resistors and open-drain outputs can be assigned by software.

In addition, R4 serves the functions of the various following special features.

Port pin	Alternate function
R41	INT2 (External Interrupt 2 Request input)
R42	X _{OUT}
R43	X _{IN}
R44	INT3 (External Interrupt 3 Request input)
R45	SX _{IN}
R46	SX _{OUT}
R47	RESET

R50~R57: R5 is an 8-bit CMOS bidirectional I/O port or LCD segment output. Each pins 1 or 0 written to the Port Direction Register can be used as outputs or inputs. And each pins can also be set in segment output mode in 1-bit

units by R5PSR Register.

Port pin	Alternate function
R50	SEG0 (Segment Output 0) / RX0
R51	SEG1 (Segment Output 1) / TX0
R52	SEG2 (Segment Output 2) / ACK
R53	SEG3 (Segment Output 3)
R54	SEG4 (Segment Output 4)
R55	SEG5 (Segment Output 5)
R56	SEG6 (Segment Output 6)
R57	SEG7 (Segment Output 7)

R60~R67: R6 is an 8-bit CMOS bidirectional I/O port or LCD segment output. Each pins 1 or 0 written to the Port Direction Register can be used as outputs or inputs. And each pins can also be set in segment output mode in 1-bit units by R6PSR Register.

Port pin	Alternate function
R60	SEG8 (Segment Output 8)
R61	SEG9 (Segment Output 9)
R62	SEG10 (Segment Output 10)
R63	SEG11 (Segment Output 11)
R64	SEG12 (Segment Output 12)
R65	SEG13 (Segment Output 13)
R66	SEG14 (Segment Output 14)
R67	SEG15 (Segment Output 15)

R70~R77: R7 is a 4-bit CMOS input port or LCD segment output. Each pins can be set in digital input or segment output mode in 1-bit units by R7PSR Register

r.

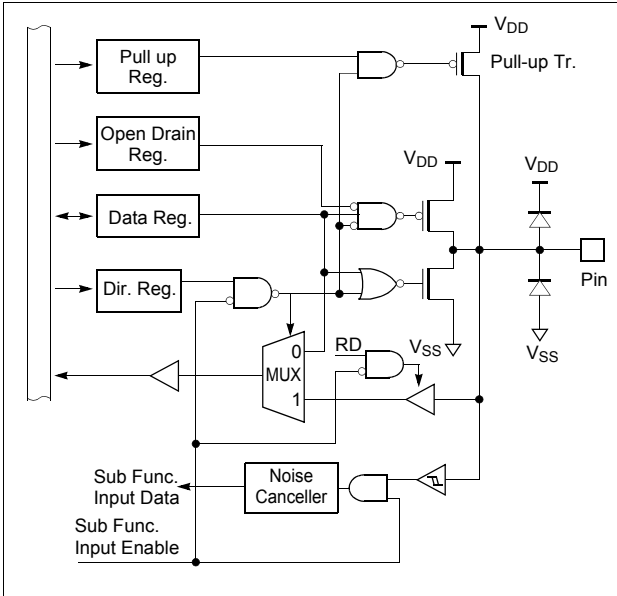

Port pin	Alternate function
R70	SEG16 (Segment Output 0) / COM7 (Common Output 7) /
R71	SEG17 (Segment Output 1) / COM6 (Common Output 6) /
R72	SEG18 (Segment Output 2) / COM5 (Common Output 5) /
R73	SEG19 (Segment Output 3) / COM4 (Common Output 4)
R74	COM3 (Common Output 3)
R75	COM2 (Common Output 2)
R76	COM1 (Common Output 1)
R77	COM0 (Common Output 0)

PIN NAME	Pin No.		Primary Function		Secondary Function		State @ Reset	State @ STOP
	MC80F7708Q	MC80F7708K	I/O	Description	I/O	Description		
V _{DD}	3	8	-	Supply Voltage	-	-	-	-
V _{SS}	4	9	-	Circuit Ground	-	-	-	-
RESET / R47	11	16	I	Reset (low active)	-	-	'L' input	'H' input
X _{IN} /R43, X _{OUT} /R42	7,6	12,11	I,O	Main clock oscillator	-	-	Oscillation	'L', 'H'
SX _{IN} /R45, SX _{OUT} /R46	9,10	14,15	I,O	Sub clock oscillator	-	-	Oscillation	
R53/SEG3 ~ R57/SEG7	17~21	22~26	I/O	General I/O port	O	LCD segment output	Input port	State of before STOP
R60/SEG8 ~ R67/SEG15	22~29	27~34	I/O	General I/O port	O	LCD segment output		
R70/SEG16/ COM7 ~ R73/SEG19/ COM4	30~33	35~38	I/O	General I/O ports	O	LCD segment output LCD common output		
R74/COM3 ~ R77/COM0	34~37	39~42	I/O	General I/O ports	O	LCD common output		
R01/EC0	44	5	I/O	General I/O port	I	Event Counter Input		
R04/BUZO	2	7	I/O		O	Buzzer Output		
R06/INT0	1	6	I/O		I	Interrupt Input		
R07/INT1	12	17	I/O		I	Interrupt Input		
R10/PWM1/ T2O	13	18	I/O		O	Timer3 PWM Output Timer2 Output		
R20/AN0 ~ R23/AN3	43~40	4~1	I/O		I	A/D Converter Analog Input		
R24/AN4 ~ R25/AN5	39,38	-	I/O		I	A/D Converter Analog Input		
R50/SEG0/RX0	14	19	I/O	General I/O ports	O I	LCD Segment Output UART0 Data Input		
R51/SEG1/TX0	15	20	I/O	General I/O ports	O	LCD Segment Output UART0 Data Output		
R52/SEG2/ACK	16	21	I/O	General I/O ports	O	LCD Segment Output UART0 external clock input

R50/SEG0/RX0, R52/SEG2/ACK

R51/SEG1/TX0

7. ELECTRICAL CHARACTERISTICS

7.1 Absolute Maximum Ratings

Supply voltage -0.3 to +6.0 V
 Storage Temperature -45 to +125 °C
 Voltage on any pin with respect to Ground (V_{SS})
 -0.3 to $V_{DD}+0.3$
 Maximum current sunk by (I_{OL} per I/O Pin) 20 mA
 Maximum output current sourced by (I_{OH} per I/O Pin)
 15 mA
 Maximum current (ΣI_{OL}) 100 mA

Maximum current (ΣI_{OH}) 60 mA

Note: Stresses above those listed under “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress rating only and functional operation of the device at any other conditions above those indicated in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

7.2 Recommended Operating Conditions

Parameter	Symbol	Condition	Specifications			Unit
			Min.	Typ.	Max.	
Supply Voltage	V_{DD}	$f_{MAIN}=4MHz$	2.2	-	5.5	V
Main Operating Frequency	f_{MAIN}	$V_{DD}^1=2.2\sim 5.5V$	0.4	-	4.0	MHz
		$V_{DD}=4.5\sim 5.5V$	0.4	-	12.0	
Sub Operating Frequency	f_{SUB}	$V_{DD}=V_{DD}$	-	32.768	-	kHz
Operating Temperature	T_{OPR}		-40	-	85	°C

1. FLASH MCU Operating Voltage.

7.3 DC Electrical Characteristics

($T_A = -40 \sim 85^\circ\text{C}$, $V_{DD} = 2.2 \sim 5.5\text{V}$, $V_{SS} = 0\text{V}$)

Parameter	Symbol	Pin / Condition	Specifications			Unit
			Min.	Typ.	Max.	
Input High Voltage	V_{IH1}	R0~R7	$0.7V_{DD}$	-	$V_{DD}+0.3$	V
	V_{IH2}	$\overline{\text{RESET}}$, X_{IN} , SX_{IN} , INT0~3, EC0	$0.8V_{DD}$	-	$V_{DD}+0.3$	
Input Low Voltage	V_{IL1}	R0~R7	-0.3	-	$0.3V_{DD}$	V
	V_{IL2}	$\overline{\text{RESET}}$, X_{IN} , SX_{IN} , INT0~3, EC0	-0.3	-	$0.2V_{DD}$	
Output High Voltage	V_{OH1}	R0~R4 ($V_{DD}=4.5\text{V}$, $I_{OH1}=-1.6\text{mA}$)	$V_{DD}-0.3$	-	-	V
	V_{OH2}	R5~R7 ($V_{DD}=4.5\text{V}$, $I_{OH2}=-1.6\text{mA}$)	$V_{DD}-1.0$	-	-	
	V_{OH3}^1	SEG0~19, COM0~3 ($V_{DD}=4.5\text{V}$, $V_{CL3-0}=3\text{V}$, $I_{OH3}=-15\mu\text{A}$)	$V_{CL3}-0.4$	-	-	
Output Low Voltage	V_{OL1}	R0~R4 ($V_{DD}=4.5\text{V}$, $I_{OL1}=1.6\text{mA}$)	-	-	0.35	V
	V_{OL2}	R5~R7 ($V_{DD}=4.5\text{V}$, $I_{OL2}=1.6\text{mA}$)	-	-	0.4	
	V_{OL3}^2	SEG0~19, COM0~3 ($V_{DD}=4.5\text{V}$, $V_{CL3-0}=3\text{V}$, $I_{OL3}=15\mu\text{A}$)	-	-	0.12	
Input High Leakage Current	I_{IH}	All input pins including R5~R7 ($V_{IN}=V_{DD}$)	-	-	1	μA
Input Low Leakage Current	I_{IL}	All input pins including R5~R7 ($V_{IN}=V_{SS}$)	-1	-	-	
Built in Reset	V_{BIR}	V_{DD} (TRM<1:0>=00)	TBD	TBD	TBD	
POR(Power on Reset) Level	V_{POR}	V_{DD} ($T_A=25^\circ\text{C}$)	2.1	2.4	2.7	V
POR Start Voltage ³	V_{START}	V_{DD} ($T_A=25^\circ\text{C}$)			1.8	V
POR Rising Time ³	T_{POR}	V_{DD} ($T_A=25^\circ\text{C}$)			40	ms/V
VDD rising Time ³	T_{VDD}	V_{DD} ($T_A=25^\circ\text{C}$)			40	ms/V
Hysteresis	$V_{T+} \sim V_{T-}$	$\overline{\text{RESET}}$, INT0~3, EC0 ($V_{DD}=5\text{V}$)	$0.2V_{DD}$	-	$0.8V_{DD}$	V
Pull-up Current	I_{PU}	R0~R4 ($V_{DD}=3.0\text{V}$, $V_{PIN}=0\text{V}$)	20	-	60	μA
Current dissipation in active mode ⁴	I_{DD}	V_{DD} ($f_{MAIN}=8\text{MHz}$, $V_{DD}=5.5\text{V}$, $f_{SUB}=0$)	-	6	15	mA
Current dissipation in sleep mode ⁵	I_{SLEEP}	V_{DD} ($f_{MAIN}=8\text{MHz}$, $V_{DD}=5.5\text{V}$, $f_{SUB}=0$)	-	2	4	
Current dissipation in stop mode	I_{STOP}	$f_{MAIN}=\text{off}$, $V_{DD}=5.5\text{V}$, $f_{SUB}=0$	-	3	7	μA
	I_{SUB}	$f_{MAIN}=\text{off}$, $V_{DD}=5.5\text{V}$, $f_{SUB}=32.768\text{kHz}$	-	10	TBD	μA
Internal 8MHz Oscillation Frequency	f_{IN8M}	$V_{DD}=5\text{V}$, $T_A=25^\circ\text{C}$	TBD	8	TBD	MHz
Internal 4MHz Oscillation Frequency	f_{IN4M}	$V_{DD}=5\text{V}$, $T_A=25^\circ\text{C}$	TBD	4	TBD	MHz

1. V_{OH3} is the voltage when VCL3, VCL2, VCL1 and VCL0 are supplied at pads.

2. V_{OL3} is the voltage when V_{SS} is supplied at pad.

3. These parameters are presented for design guidance only and not tested or guaranteed.

4. Current dissipation is proportioned according to operation voltage and frequency.

5. In sleep mode, oscillation continues and peripherals are operated normally but internal CPU clock stops.

7.4 LCD Characteristics

($T_A = -40 \sim 85^\circ\text{C}$, $V_{DD} = 2.2 \sim 5.5\text{V}$, $V_{SS} = 0\text{V}$)

Parameter	Symbol	Condition	Specifications			Unit
			Min.	Typ.	Max.	
LCD Common Output Current	I_{COM}	Output Voltage Deviation=0.2V	30	-	-	μA
LCD Segment Output Current	I_{SEG}	Output Voltage Deviation=0.2V	5	-	-	

7.5 A/D Converter Characteristics

($T_A = 25^\circ\text{C}$, $V_{DD} = 3.072\text{V}@f_{XIN} = 4\text{MHz}$, $V_{DD} = 5.12\text{V}@f_{XIN} = 8\text{MHz}$, $V_{SS} = 0\text{V}$)

Parameter	Symbol	Pin/Condition	Specifications			Unit
			Min.	Typ.	Max.	
Conversion Current	I_{CON}	-	-	TBD	-	mA
Analog Power Supply Input Voltage Range	AV_{DD}^1	V_{DD}	2.7	-	5.5	V
Analog Input Voltage Range	V_{AIN}	AN0 ~ AN5	$V_{SS} - 0.3$	-	$V_{DD} + 0.3$	
Resolution	N_R	-	10			Bit
Input Impedance	$IN[7:0]$	AN0 ~ AN5	1	-	-	$M\Omega$

Figure 7-1 AC Timing Chart

7.7 Typical Characteristics

These graphs and tables are for design guidance only and are not tested or guaranteed.

In some graphs or tables, the data presented are outside specified operating range (e.g. outside specified V_{DD} range). This is for information only and devices are guaranteed to operate properly only within the specified range.

The data is a statistical summary of data collected on units from different lots over a period of time. “Typical” repre-

sents the mean of the distribution while “max” or “min” represents $(\text{mean} + 3\sigma)$ and $(\text{mean} - 3\sigma)$ respectively where σ is standard deviation

8. MEMORY ORGANIZATION

The have separate address spaces for Program memory, Data Memory and Display memory. Program memory can only be read, not written to. It can be up to 8K bytes of Pro-

gram memory. Data memory can be read and written to up to 1024 bytes including the stack area. Display memory has prepared 27 nibbles for LCD.

8.1 Registers

This device has six registers that are the Program Counter (PC), a Accumulator (A), two index registers (X, Y), the Stack Pointer (SP), and the Program Status Word (PSW). The Program Counter consists of 16-bit register.

Figure 8-1 Configuration of Registers

Accumulator: The Accumulator is the 8-bit general purpose register, used for data operation such as transfer, temporary saving, and conditional judgement, etc.

The Accumulator can be used as a 16-bit register with Y Register as shown below.

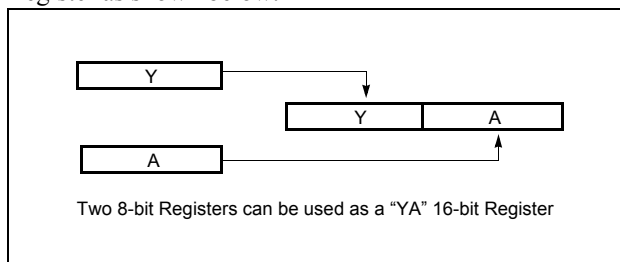

Figure 8-2 Configuration of YA 16-bit Register

X, Y Registers: In the addressing mode which uses these index registers, the register contents are added to the specified address, which becomes the actual address. These modes are extremely effective for referencing subroutine tables and memory tables. The index registers also have increment, decrement, comparison and data transfer functions, and they can be used as simple accumulators.

Stack Pointer: The Stack Pointer is an 8-bit register used for occurrence interrupts and calling out subroutines. Stack Pointer identifies the location in the stack to be accessed (save or restore).

Generally, SP is automatically updated when a subroutine call is executed or an interrupt is accepted. However, if it is used in excess of the stack area permitted by the data memory allocating configuration, the user-processed data may be lost.

The stack can be located at any position within 100H to 15FH of the internal data memory. The SP is not initialized by hardware, requiring to write the initial value (the location with which the use of the stack starts) by using the initialization routine. Normally, the initial value of "15FH" is used.

Caution:

The Stack Pointer must be initialized by software because its value is undefined after RESET.

Example: To initialize the SP

```
LDX #05FH ;
TXSP ; SP ← 05FH
```

Program Counter: The Program Counter is a 16-bit wide which consists of two 8-bit registers, PCH and PCL. This counter indicates the address of the next instruction to be executed. In reset state, the program counter has reset routine address (PCH:0FFH, PCL:0FEH).

Program Status Word: The Program Status Word (PSW) contains several bits that reflect the current state of the CPU. The PSW is described in Figure 8-3. It contains the Negative flag, the Overflow flag, the Break flag the Half Carry (for BCD operation), the Interrupt enable flag, the Zero flag, and the Carry flag.

[Carry flag C]

This flag stores any carry or borrow from the ALU of CPU after an arithmetic operation and is also changed by the Shift Instruction or Rotate Instruction.

[Zero flag Z]

This flag is set when the result of an arithmetic operation or data transfer is “0” and is cleared by any other result.

Figure 8-3 PSW (Program Status Word) Register

[Interrupt disable flag I]

This flag enables/disables all interrupts except interrupt caused by Reset or software BRK instruction. All interrupts are disabled when cleared to “0”. This flag immediately becomes “0” when an interrupt is served. It is set by the EI instruction and cleared by the DI instruction.

[Half carry flag H]

After operation, this is set when there is a carry from bit 3 of ALU or there is no borrow from bit 4 of ALU. This bit can not be set or cleared except CLR_V instruction with Overflow flag (V).

[Break flag B]

This flag is set by software BRK instruction to distinguish BRK from T_{CALL} instruction with the same vector address.

[Direct page flag G]

This flag assigns RAM page for direct addressing mode. In

the direct addressing mode, addressing area is from zero page 00_H to 0FF_H when this flag is “0”. If it is set to “1”, addressing area is assigned by RPR register (address 0F3_H). It is set by SET_G instruction and cleared by CLR_G.

[Overflow flag V]

This flag is set to “1” when an overflow occurs as the result of an arithmetic operation involving signs. An overflow occurs when the result of an addition or subtraction exceeds +127 (7F_H) or -128 (80_H). The CLR_V instruction clears the overflow flag. There is no set instruction. When the BIT instruction is executed, bit 6 of memory is copied to this flag.

[Negative flag N]

This flag is set to match the sign bit (bit 7) status of the result of a data or arithmetic operation. When the BIT instruction is executed, bit 7 of memory is copied to this flag.

Figure 8-4 Stack Operation

8.2 Program Memory

A 16-bit program counter is capable of addressing up to 64K bytes, but this device has 8K bytes program memory space only physically implemented. Accessing a location above FFFF_H will cause a wrap-around to 0000_H.

Figure 8-5 shows a map of Program Memory. After reset, the CPU begins execution from reset vector which is stored in address FFFE_H and FFFF_H as shown in Figure 8-6.

As shown in Figure 8-5, each area is assigned a fixed location in Program Memory. Program Memory area contains the user program.

Figure 8-5 Program Memory Map

Page Call (PCALL) area contains subroutine program to reduce program byte length by using 2 bytes PCALL instead of 3 bytes CALL instruction. If it is frequently called, it is more useful to save program byte length.

Table Call (TCALL) causes the CPU to jump to each TCALL address, where it commences the execution of the service routine. The Table Call service area spaces 2-byte for every TCALL: 0FFC0_H for TCALL15, 0FFC2_H for TCALL14, etc., as shown in Figure 8-7.

Example: Usage of TCALL

```

LDA    #5
TCALL  0FH      ; 1BYTE INSTRUCTION
:
:              ; INSTEAD OF 2 BYTES
:              ; NORMAL CALL

; TABLE CALL ROUTINE
;
FUNC_A: LDA    LRG0
        RET
;
FUNC_B: LDA    LRG1
        RET
;
; TABLE CALL ADD. AREA
;
ORG    0FFC0H  ; TCALL ADDRESS AREA
DW     FUNC_A
DW     FUNC_B
    
```

The interrupt causes the CPU to jump to specific location, where it commences the execution of the service routine. The External interrupt 0, for example, is assigned to location 0FFFA_H. The interrupt service locations spaces 2-byte interval: 0FFF8_H and 0FFF9_H for External Interrupt 1, 0FFFA_H and 0FFFB_H for External Interrupt 0, etc.

Any area from 0FF00_H to 0FFFF_H, if it is not going to be used, its service location is available as general purpose Program Memory.

8.3 Data Memory

Figure 8-8 shows the internal Data Memory space available. Data Memory is divided into four groups, a user RAM, control registers, Stack, and LCD memory.

Figure 8-8 Data Memory Map

User Memory

The MC80F7708 have 256×8 bits for the user data memory (RAM). There are three pages internal RAM. Page is selected by G-flag and RAM page selection register RPR. When G-flag is cleared to “0”, always page 0 is selected regardless of RPR value. If G-flag is set to “1”, page will be selected according to RPR value.

Figure 8-9 RAM page configuration

RPR (RAM Page Selection Register)

ADDRESS: 0CF_H
INITIAL VALUE: ----_001_B

RPR[2:0] (RAM Page Selection)

RPR2	RPR1	RPR0	RAM Page Selection
0	0	0	PAGE 0
0	0	1	PAGE 1
0	1	0	-
0	1	1	-
1	0	0	PAGE 4
1	0	1	-
1	1	0	-
1	1	1	-

Caution1 : After setting RPR, be sure to execute SETG instruction.
Caution2 : When executing CLRG instruction, be selected PAGE0 regardless of RPR.

Figure 8-10 RAM Page Selection Register

Control Registers

The control registers are used by the CPU and Peripheral function blocks for controlling the desired operation of the device. Therefore these registers contain control and status bits for the interrupt system, the timer/counters, analog to digital converters and I/O ports. The control registers are in address range of 0A0_H to 0FF_H.

Note that unoccupied addresses may not be implemented on the chip. Read accesses to these addresses will in general return random data, and write accesses will have an indeterminate effect.

More detailed informations of each register are explained in each peripheral section.

Note: Write only registers can not be accessed by bit manipulation instruction. Do not use read-modify-write instruction. Use byte manipulation instruction.

Example; To write at CKCTRL

```
LDM CKCTRL, #05H ;Divide ratio ÷8
```

Stack Area

The stack provides the area where the return address is saved before a jump is performed during the processing

routine at the execution of a subroutine call instruction or the acceptance of an interrupt.

When returning from the processing routine, executing the subroutine return instruction [RET] restores the contents of the program counter from the stack; executing the interrupt return instruction [RETI] restores the contents of the program counter and flags.

The save/restore locations in the stack are determined by

the stack pointer (SP). The SP is automatically decreased after the saving, and increased before the restoring. This means the value of the SP indicates the stack location number for the next save. Refer to Figure 8-4 on page 23.

LCD Display Memory

LCD display data area is handled in LCD section.

See "18.3 LCD Display Memory" on page 80.

Table 8-1 Control Registers

1. "byte", "bit" means that register can be addressed by not only bit but byte manipulation instruction.
2. "byte" means that register can be addressed by only byte manipulation instruction. On the other hand, do not use any read-modify-write instruction such as bit manipulation.
3. bit 0 of ADCM is read only.

8.4 Addressing Mode

The MC80F7708 use six addressing modes;

- Register addressing
- Immediate addressing
- Direct page addressing
- Absolute addressing
- Indexed addressing
- Register-indirect addressing

(1) Register Addressing

Register addressing accesses the A, X, Y, C and PSW.

(2) Immediate Addressing → #imm

In this mode, second byte (operand) is accessed as a data immediately.

Example:

```
0435   ADC   #35H
```

When G-flag is 1, then RAM address is defined by 16-bit address which is composed of 8-bit RAM paging register (RPR) and 8-bit immediate data.

Example: G=1, RPR=01H

```
E45535  LDM   35H, #55H
```

(3) Direct Page Addressing → dp

In this mode, a address is specified within direct page.

Example; G=0

```
C535   LDA   35H           ;A ←RAM[35H]
```

(4) Absolute Addressing → !abs

Absolute addressing sets corresponding memory data to Data, i.e. second byte (Operand I) of command becomes lower level address and third byte (Operand II) becomes upper level address.

With 3 bytes command, it is possible to access to whole memory area.

ADC, AND, CMP, CMPX, CMPY, EOR, LDA, LDX, LDY, OR, SBC, STA, STX, STY

Example;

```
0735F0  ADC   !0F035H     ;A ←ROM[0F035H]
```

The operation within data memory (RAM)
ASL, BIT, DEC, INC, LSR, ROL, ROR

Example; Addressing accesses the address 0135H regardless of G-flag and RPR.

```
981501 INC !0115H ;A ←ROM[115H]
```

X indexed direct page, auto increment → {X}+

In this mode, a address is specified within direct page by the X register and the content of X is increased by 1.

LDA, STA

Example; G=0, X=35H

```
DB LDA {X}+
```

(5) Indexed Addressing

X indexed direct page (no offset) → {X}

In this mode, a address is specified by the X register.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA, XMA

Example; X=15H, G=1, RPR=01H

```
D4 LDA {X} ;ACC←RAM[X].
```

X indexed direct page (8 bit offset) → dp+X

This address value is the second byte (Operand) of command plus the data of X-register. And it assigns the memory in Direct page.

ADC, AND, CMP, EOR, LDA, LDY, OR, SBC, STA STY, XMA, ASL, DEC, INC, LSR, ROL, ROR

Example; G=0, X=0F5H

```
C645 LDA 45H+X
```

Y indexed direct page (8 bit offset) → dp+Y

This address value is the second byte (Operand) of command plus the data of Y-register, which assigns Memory in Direct page.

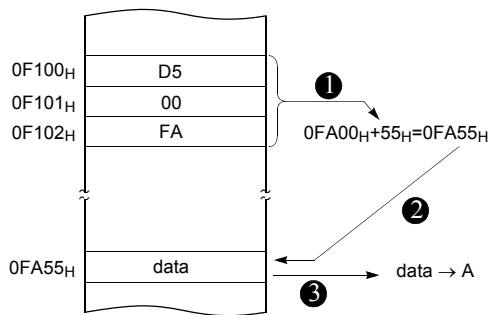

This is same with above. Use Y register instead of X.

Y indexed absolute → !abs+Y

Sets the value of 16-bit absolute address plus Y-register data as Memory. This addressing mode can specify memory in whole area.

Example; Y=55H

```
D500FA LDA !0FA00H+Y
```

```
3F35 JMP [35H]
```

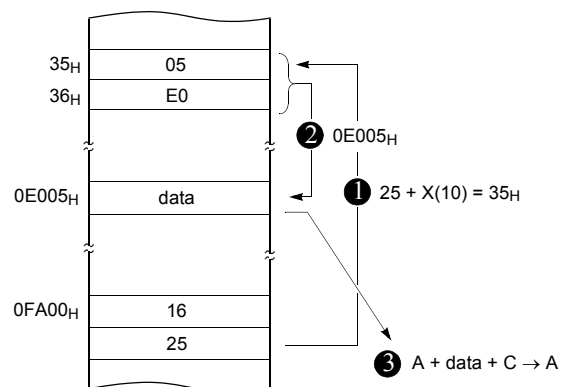

X indexed indirect → [dp+X]

Processes memory data as Data, assigned by 16-bit pair memory which is determined by pair data [dp+X+1][dp+X] Operand plus X-register data in Direct page.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA

Example; G=0, X=10H

```
1625 ADC [25H+X]
```

(6) Indirect Addressing

Direct page indirect → [dp]

Assigns data address to use for accomplishing command which sets memory data (or pair memory) by Operand. Also index can be used with Index register X, Y.

JMP, CALL

Example; G=0

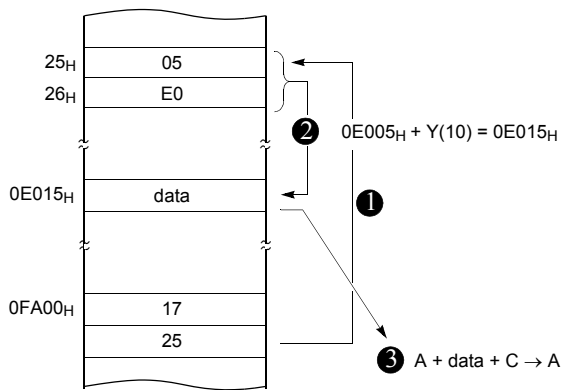

Y indexed indirect → [dp]+Y

Processes memory data as Data, assigned by the data [dp+1][dp] of 16-bit pair memory paired by Operand in Direct page plus Y-register data.

ADC, AND, CMP, EOR, LDA, OR, SBC, STA

Example; G=0, Y=10H

```
1725   ADC   [25H]+Y
```

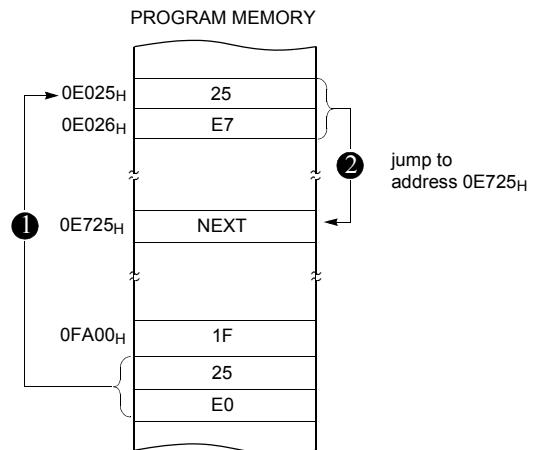

Absolute indirect → [!abs]

The program jumps to address specified by 16-bit absolute address.

JMP

Example; G=0

```
1F25E0   JMP   [!0E025H]
```

9. I/O PORTS

The MC80F7708 have seven I/O ports, LCD segment ports (R0, R1, R2, R4, R50/SEG0/RX0 ~ R73/SEG19/COM4) and LCD common ports (R77/COM0 ~ R74/COM3, R73/SEG19/COM4 ~ R70/SEG16/COM7).

9.1 Registers for Ports

Port Data Registers

The Port Data Registers are represented as a D-Type flip-flop, which will clock in a value from the internal bus in response to a “write to data register” signal from the CPU. The Q output of the flip-flop is placed on the internal bus in response to a “read data register” signal from the CPU. The level of the port pin itself is placed on the internal bus in response to “read data register” signal from the CPU. Some instructions that read a port activating the “read register” signal, and others activating the “read pin” signal.

Port Direction Registers

All pins have data direction registers which can define these ports as output or input. A “1” in the port direction register configure the corresponding port pin as output. Conversely, write “0” to the corresponding bit to specify it as input pin. For example, to use the even numbered bit of R0 as output ports and the odd numbered bits as input ports, write “55H” to address 0C1H (R0 port direction register) during initial setting as shown in Figure 9-1.

All the port direction registers in the MC80F7708 have 0 written to them by reset function. Therefore, its initial status is input.

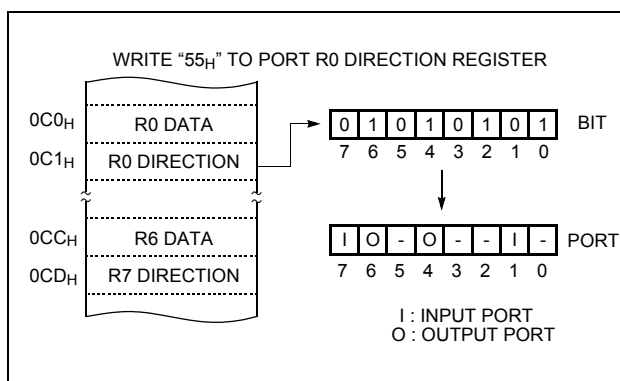

Figure 9-1 Example of port I/O assignment

Pull-up Control Registers

The R0, R1, R2 and R4 ports have internal pull-up resistors. Figure 9-2 shows a functional diagram of a typical

pull-up port. It is connected or disconnected by Pull-up Control register (RnPU). The value of that resistor is typically 100kΩ. Refer to DC characteristics for more details.

When a port is used as key input, input logic is firmly either low or high, therefore external pull-down or pull-up resistors are required practically. The MC80F7708 have internal pull-up, it can be logic high by pull-up that can be able to configure either connect or disconnect individually by pull-up control registers RnPU.

When ports are configured as inputs and pull-up resistor is selected by software, they are pulled to high.

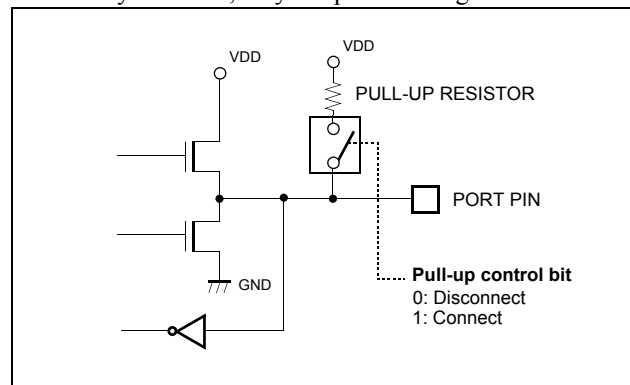

Figure 9-2 Pull-up Port Structure

Open drain port Registers

The R0, R1, R2 and R4 ports have open drain port resistors R0OD~R4OD.

Figure 9-3 shows an open drain port configuration by control register. It is selected as either push-pull port or open drain port by R0OD, R1OD, R2OD and R4OD.

Figure 9-3 Open-drain Port Structure

9.2 I/O Ports Configuration

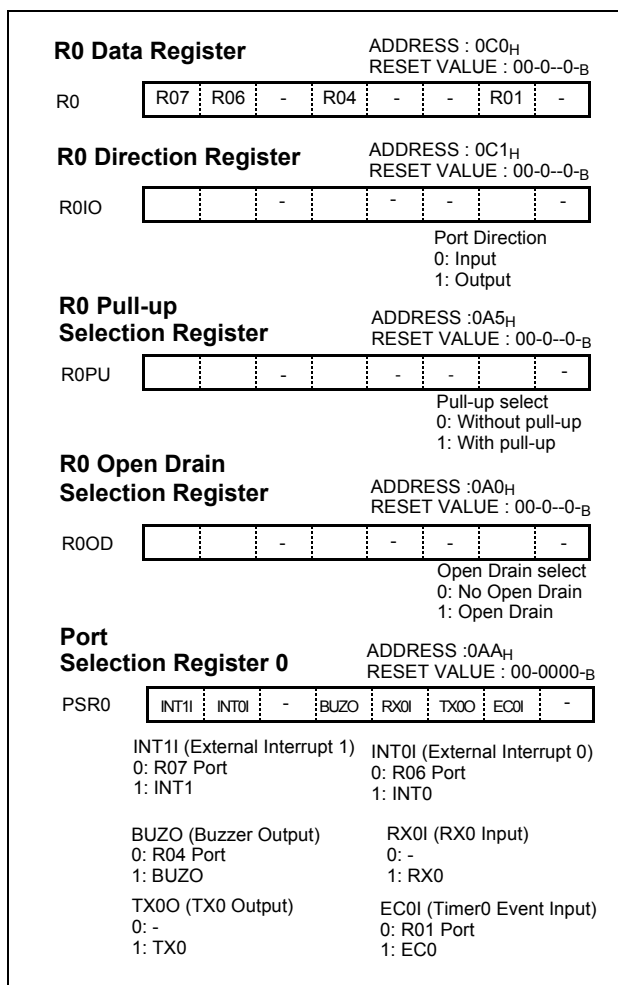

R0 Port

R0 is a 4-bit CMOS bidirectional I/O port (address 0C0_H). Each I/O pin can independently used as an input or an output through the R0IO register (address 0C1_H).

R0 has internal pull-ups that is independently connected or disconnected by R0PU. The control registers for R0 are shown below.

In addition, Port R0 is multiplexed with various special features. The control register PSR0 (address 0AA_H) controls the selection of alternate function. After reset, this value is “0”, port may be used as normal I/O port.

To use alternate function such as External Interrupt rather than normal I/O, write “1” in the corresponding bit of PSR0.

Port Pin	Alternate Function
R01	EC0 (Timer0 Event Input)
-	TX0 (TX0 Output)
-	RX0 (RX0 Input)
R04	BUZO (Buzzer Output)
R06	INT0 (External Interrupt 0)
R07	INT1 (External Interrupt 1)

Note: R0IO, R0PU, P0OD and PSR0 are write-only registers. They can not be read and can not be accessed by bit manipulation instruction. Do not use read or read-modify-write instruction. Use byte manipulation instruction.

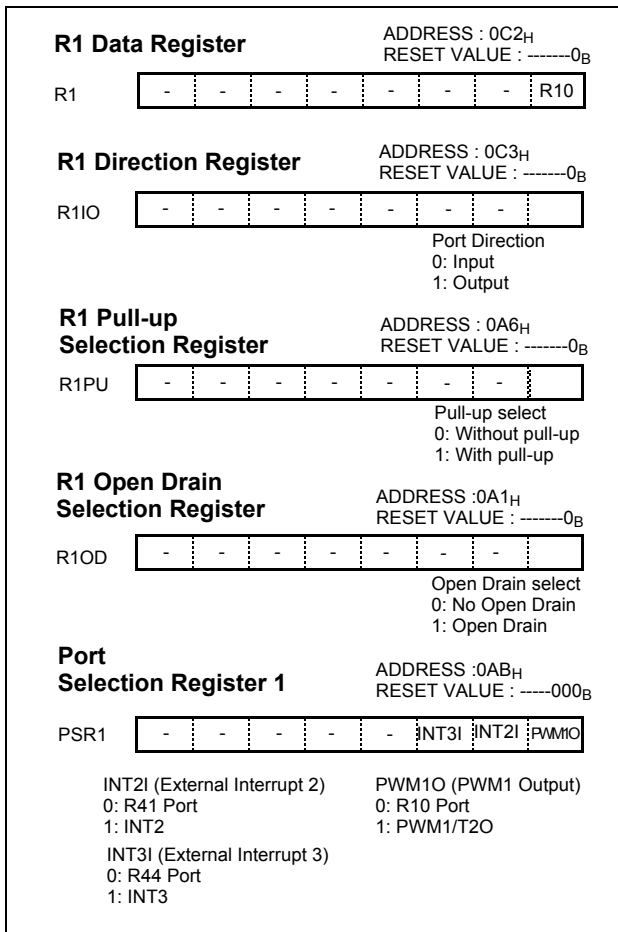

R1 Ports

R1 is an 1-bit CMOS bidirectional I/O port (address 0C2_H). Each I/O pin can independently used as an input or an output through the R1IO register (address 0C3_H).

R1 has internal pull-up that is independently connected or disconnected by register R1PU. The control registers for R1 are shown below.

Port R1 is multiplexed with two special features. The control register controls the selection of alternate function. After reset, this value is “0”, port may be used as normal I/O port. The way to select alternate function such as PWM1 or Timer Output Wave will be shown in each peripheral section.

Note: R1IO, R1PU, P1OD and PSR1 are write-only registers. They can not be read and can not be accessed by bit manipulation instruction. Do not use read or read-modify-write instruction. Use byte manipulation instruction.

R2 Ports

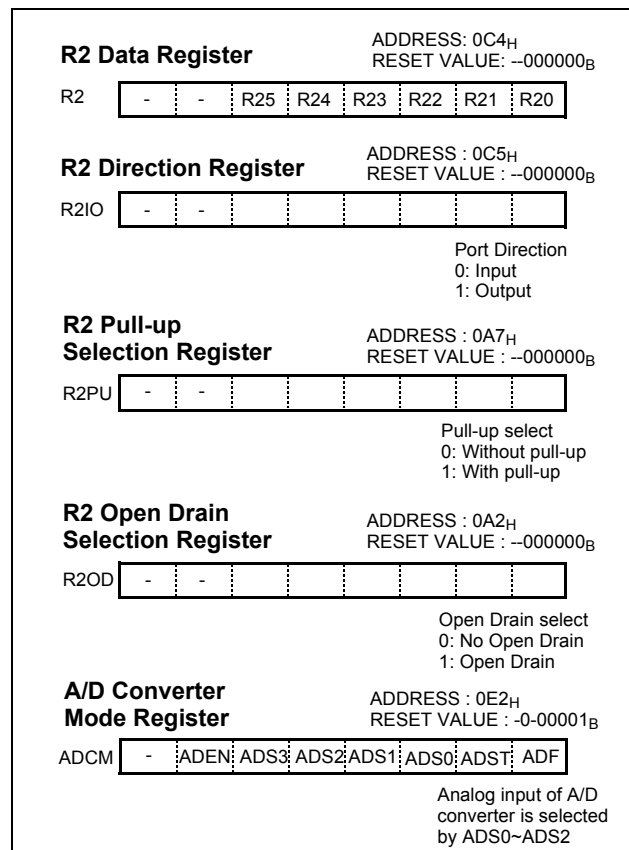

R2 is a 6-bit CMOS bidirectional I/O port (address 0C4_H). Each I/O pin can independently used as an input or an output through the R2IO register (address 0C5_H).

R2 has internal pull-ups that are independently connected or disconnected by R2PU (address 0A7_H). The control registers for R2 are shown as below.

Note: R2IO, R2PU and P2OD are write-only registers. They can not be read and can not be accessed by bit ma-

nipulation instruction. Do not use read or read-modify-write instruction. Use byte manipulation instruction.

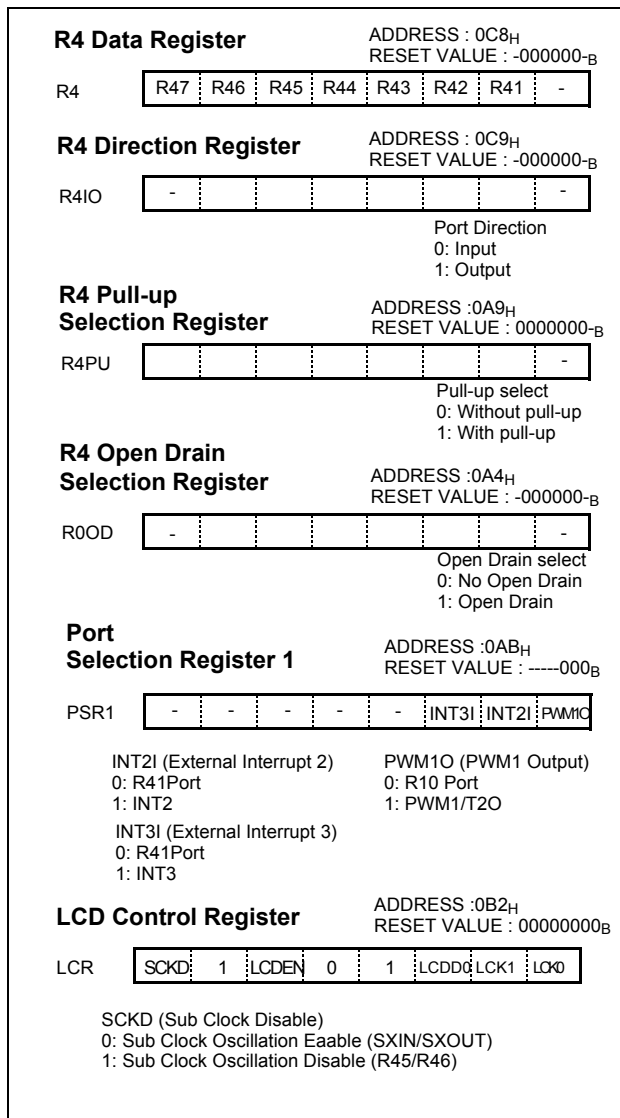

Note: The R24 and R25 are not supported in the MC80F7708K.

R4 Port

R4 is a 7-bit CMOS bidirectional I/O port (address 0C8_H). Each I/O pin can independently used as an input or an output through the R4IO register (address 0C9_H).

R4 has internal pull-ups that is independently connected or disconnected by R4PU. The control registers for R4 are shown below.

In addition, Port R4 is multiplexed with oscillation input/output, reset and interrupt input pins. The control register PSR1 (address 0AB_H) controls the selection of alternate function. After reset, this value is "0", port may be used as normal I/O port. To use alternate function such as External Interrupt rather than normal I/O, write "1" in the corresponding bit of PSR1.

Main oscillation input/output and reset pin can be used as normal I/O ports (R43/R42) and normal input port (R47) by selecting configuration options in flash writing. Sub oscillation input/output pin can be used as normal I/O ports by writing "1" to the SCKD bit of the LCR register

Port Pin	Alternate Function
R41	INT2 (External Interrupt 2)
R42	X _{OUT} (Oscillation Output)
R43	X _{IN} (Oscillation Input)
R44	INT3 (External Interrupt 3)
R45	SX _{IN} (Subsystem Oscillation Input)
R46	SX _{OUT} (Subsystem Oscillation Output)
R47	RESET (System Reset Input)

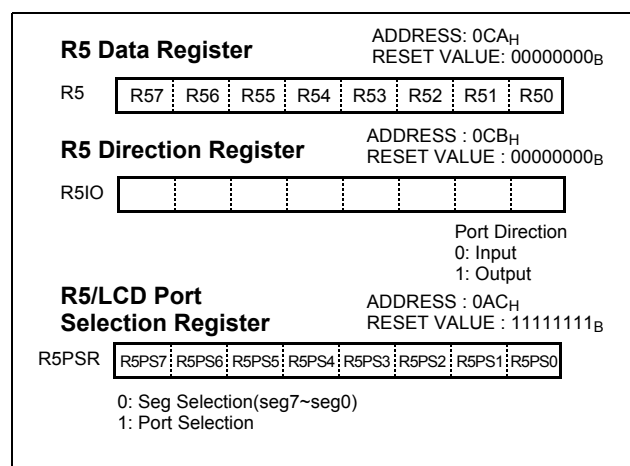

Note: R4IO, R4PU, P4OD and PSR1 are write-only registers. They can not be read and can not be accessed by bit manipulation instruction. Do not use read or read-modify-write instruction. Use byte manipulation instruction.

R5 Ports

R5 is an 8-bit CMOS bidirectional I/O port (address 0CA_H). Each I/O pin can independently used as an input or an output through the R5IO register (address 0CB_H).

R5 is multiplexed with LCD segment output (SEG0 ~ SEG7), which can be selected by writing appropriate value into the R5PSR (address 0AC_H).

R50, R1, R52 is also multiplexed with RX0, TX0 and ACK, which can be selected by writing appropriate value into the ASIMR0 (address 0B8_H).

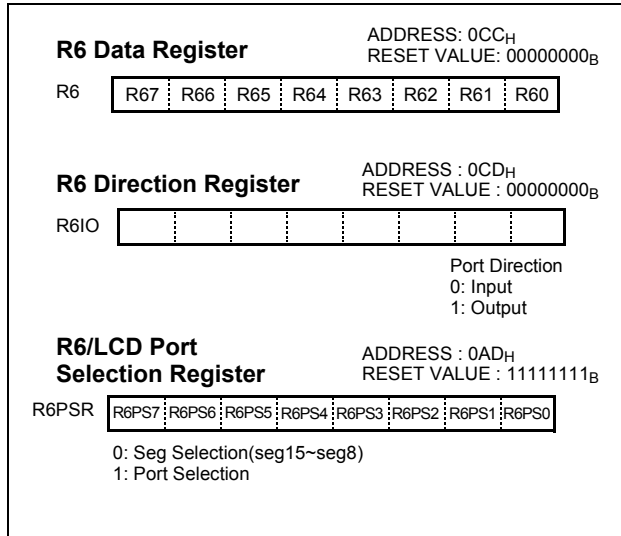

Note: R5IO is write-only register. It can not be read and can not be accessed by bit manipulation instruction. Do not use read or read-modify-write instruction. Use byte manipulation instruction.

R6 Ports

R6 is an 8-bit CMOS bidirectional I/O port (address 0CC_H). Each I/O pin can independently used as an input or an output through the R6IO register (address 0CD_H).

R6 is multiplexed with LCD segment output(SEG8 ~ SEG15), which can be selected by writing appropriate value into the R6PSR(address 0AD_H).

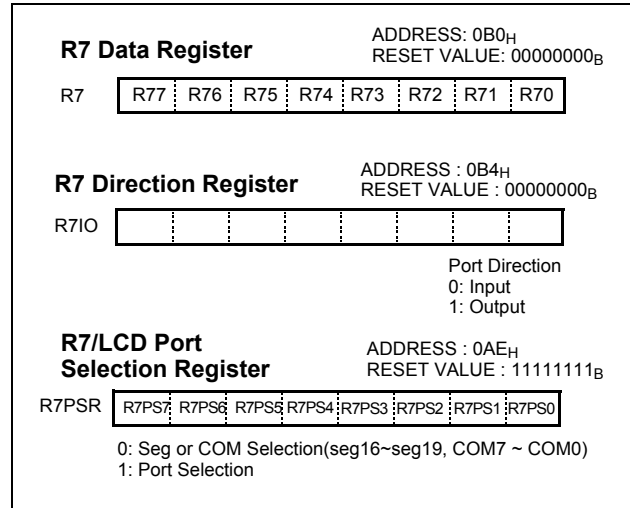

Note: R6IO is write-only register. It can not be read and can not be accessed by bit manipulation instruction. Do not use read or read-modify-write instruction. Use byte manipulation instruction.

R7 Ports

R7 is a 4-bit CMOS bidirectional I/O port (address 0B0_H). Each I/O pin can independently used as an input or an output through the R7IO register (address 0B4_H).

R7 is multiplexed with LCD common output (COM7 ~ COM0) and segment output(SEG16 ~ SEG19), which can be selected by writing appropriate value into the R7PSR(address 0AE_H) and LCR(address 0B2_H).

Note: R7IO is write-only register. It can not be read and can not be accessed by bit manipulation instruction. Do not use read or read-modify-write instruction. Use byte manipulation instruction.

SEG0~SEG19

Segment signal output pins for the LCD display. See "18. LCD DRIVER" on page 76 for details.

COM0~COM7

Common signal output pins for the LCD display. See "18. LCD DRIVER" on page 76 for details.

SEG16~SEG19 and COM7~COM4 are selected by LCDD of the LCR register.

10. CLOCK GENERATOR

As shown in Figure 10-1, the clock generator produces the basic clock pulses which provide the system clock to be supplied to the CPU and the peripheral hardware. It contains two oscillators which are main-frequency clock oscillator and a sub-frequency clock oscillator. The system clock can also be obtained from the external oscillator. By setting configuration option, the internal 8MHz, 4MHz, 2MHz can also be selected for system clock source.

The clock generator produces the system clocks forming clock pulse, which are supplied to the CPU and the peripheral hardware.

The internal system clock should be selected to main oscillation by setting bit1 and bit0 of the system clock mode register (SCMR). The registers are shown in Figure 10-2.

To the peripheral block, the clock among the not-divided original clocks, divided by 2, 4,..., up to 4096 can be provided. Peripheral clock is enabled or disabled by STOP instruction. The peripheral clock is controlled by clock control register (CKCTLR). See "11. BASIC INTERVAL TIMER" on page 42 for details.

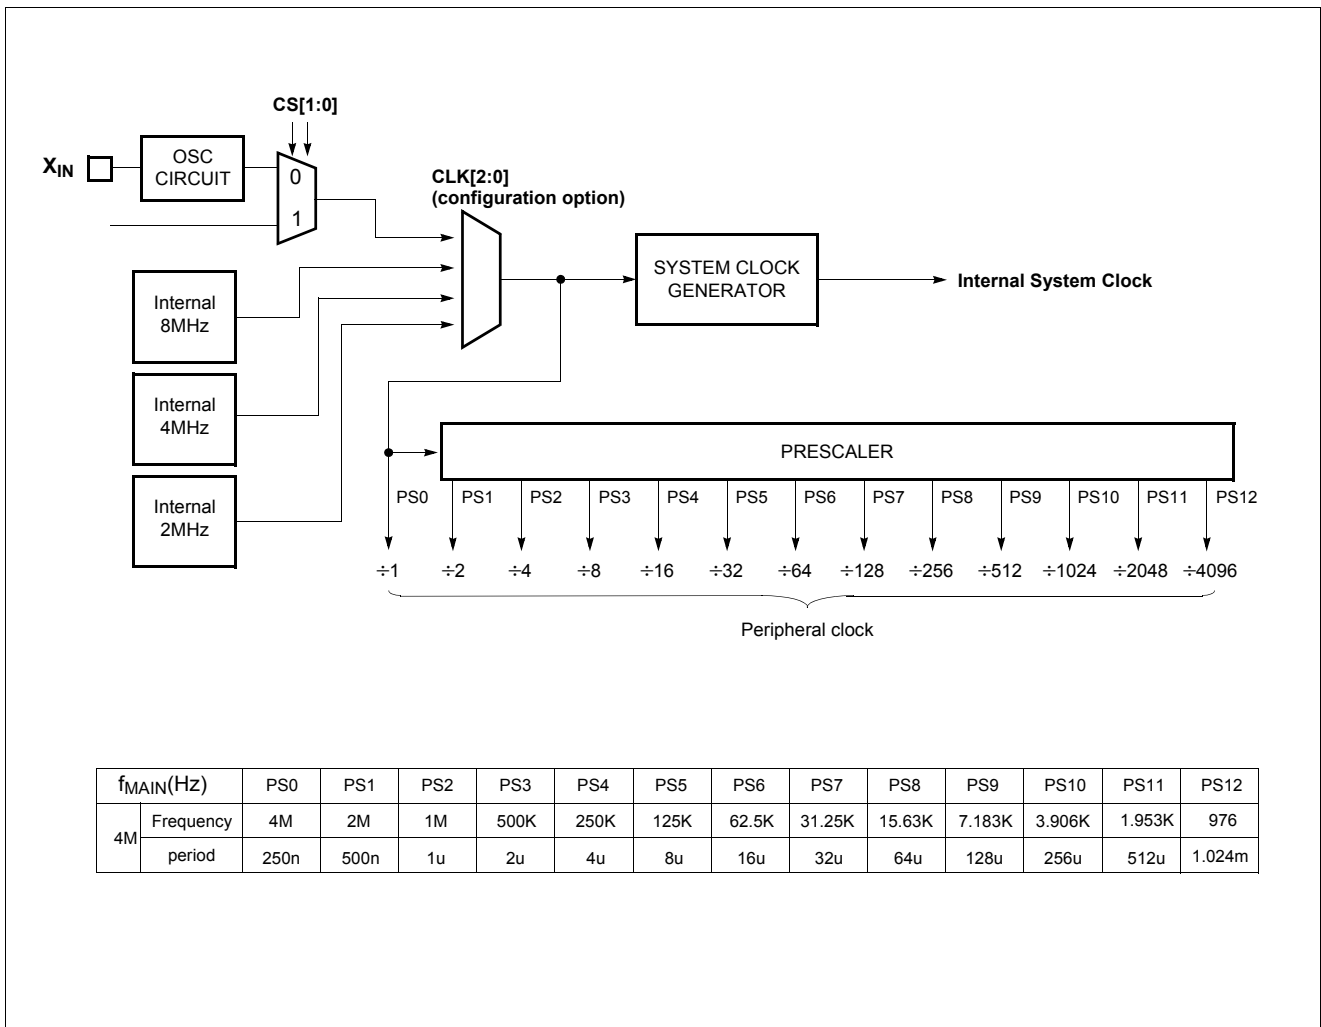

Figure 10-1 Block Diagram of Clock Generator

The SCMR should be set to operate by main oscillation. Bit2, bit1 and bit0 of the SCMR should be set to “000” or “001” to select main oscillation.

Figure 10-2 SCMR : System Clock Mode Register

11. BASIC INTERVAL TIMER

The MC80F7708 have one 8-bit Basic Interval Timer that is free-run and can not stop. Block diagram is shown in Figure 11-1.

The Basic Interval Timer Register (BITR) is increased every internal count pulse which is divided by prescaler. Since prescaler has division ratio from 8 to 1024, the count rate is 1/8 to 1/1024 of the oscillator frequency. After reset, the BCK bits are all set, so the longest oscillation stabilization time is obtained.

It also provides a Basic interval timer interrupt (BITF). The count overflow of BITR from FF_H to 00_H causes the

interrupt to be generated. The Basic Interval Timer is controlled by the clock control register (CKCTLR) shown in Figure 11-2.

Source clock can be selected by lower 3 bits of CKCTLR. When write “1” to bit BCL of CKCTLR, BITR register is cleared to “0” and restart to count up. The bit BCL becomes “0” automatically after one machine cycle by hardware.

BITR and CKCTLR are located at same address, and address 0E6_H is read as a BITR, and written to CKCTLR.

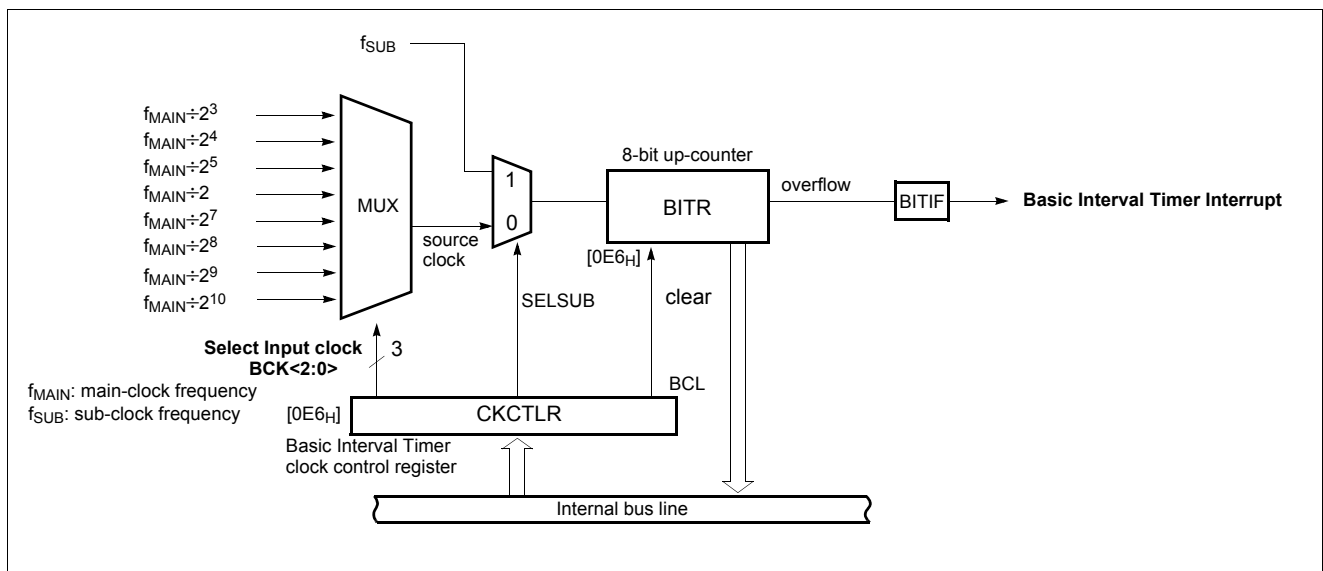

Figure 11-1 Block Diagram of Basic Interval Timer

BCK<2:0>	Source clock	Interrupt (overflow) Period
	SCMR[1:0] = 00 or 01	At f _{MAIN} = 4MHz

12. TIMER / COUNTER

Timer/Event Counter consists of prescaler, multiplexer, 8-bit timer data register, 8-bit counter register, mode register, input capture register and Comparator as shown in Figure 12-4. And the PWM high register for PWM is consisted separately.

The timer/counter has seven operating modes.

- 8 Bit Timer/Counter Mode
- 8 Bit Capture Mode
- 8 Bit Compare Output Mode
- 16 Bit Timer/Counter Mode
- 16 Bit Capture Mode
- 16 Bit Compare Output Mode
- PWM Mode

In the “timer” function, the register is increased every internal clock input. Thus, one can think of it as counting internal clock input. Since a least clock consists of 2 and

most clock consists of 2048 oscillator periods, the count rate is 1/2 to 1/2048 of the oscillator frequency in Timer0. And Timer1 can use the same clock source too. In addition, Timer1 has more fast clock source (1/1 to 1/8).

In the “counter” function, the register is increased in response to a 0-to-1 (rising edge) transition at its corresponding external input pin EC0 (Timer 0).

In addition the “capture” function, the register is increased in response external or internal clock interrupt same with timer/counter function. When external interrupt edge input, the count register is captured into capture data register TMx.

Timer3 is shared with “PWM” function and Timer2 is shared with “Compare output” function.

Table 12-1 Operating Modes of Timer 0 and Timer 1

12.1 8-Bit Timer/Counter Mode

The MC80F7708 have four 8-bit Timer/Counters, Timer0, Timer1, Timer2 and Timer3 as shown in Figure 12-4.

The “timer” or “counter” function is selected by mode registers TMx (x=0,1,2,3) as shown in Figure 12-1 and Table

12-1. To use as an 8-bit timer/counter mode, bit CAPx of TMx is cleared to “0” and bits 16BIT of TM1(3) should be cleared to “0” (Table 12-1).

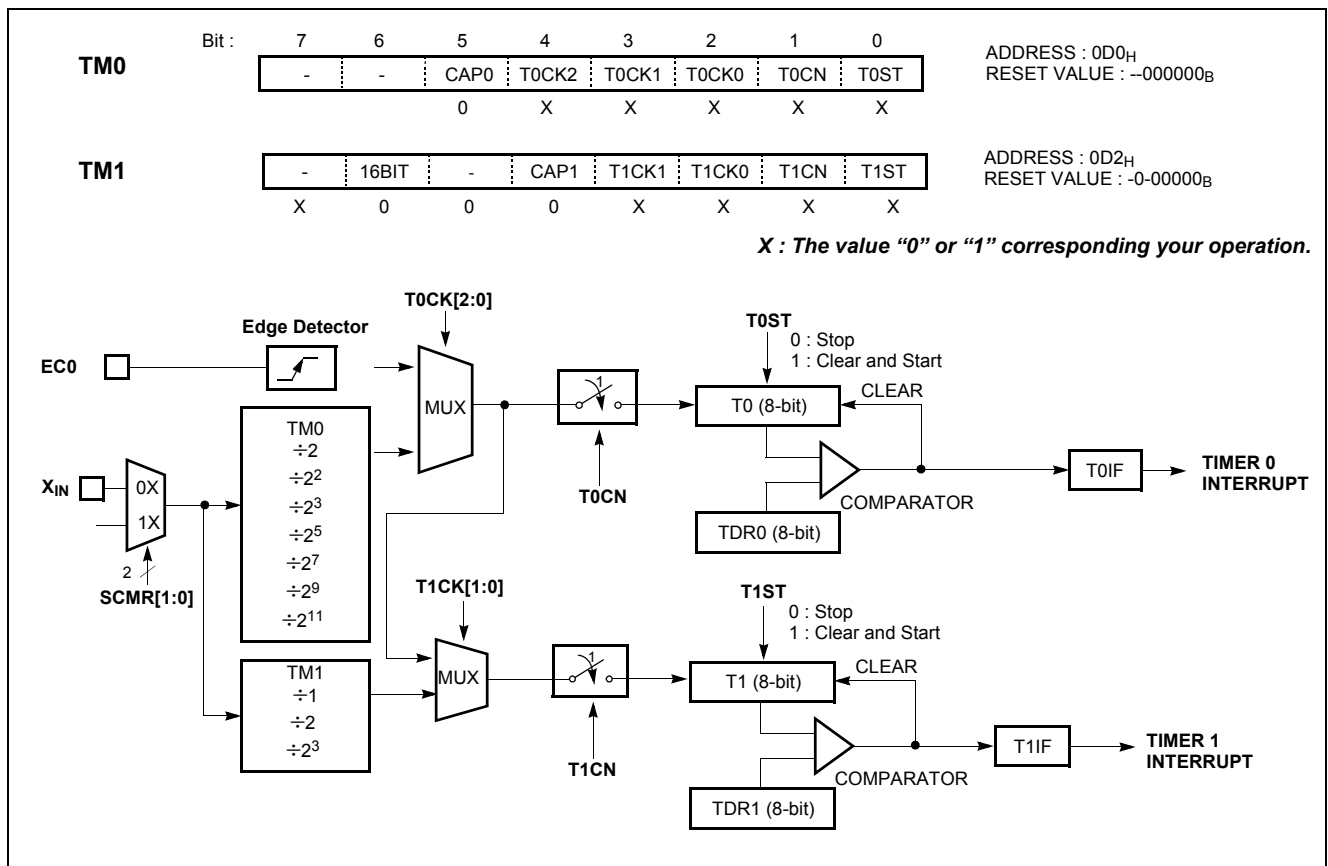

Figure 12-4 Block Diagram of Timer/Event Counter0,1

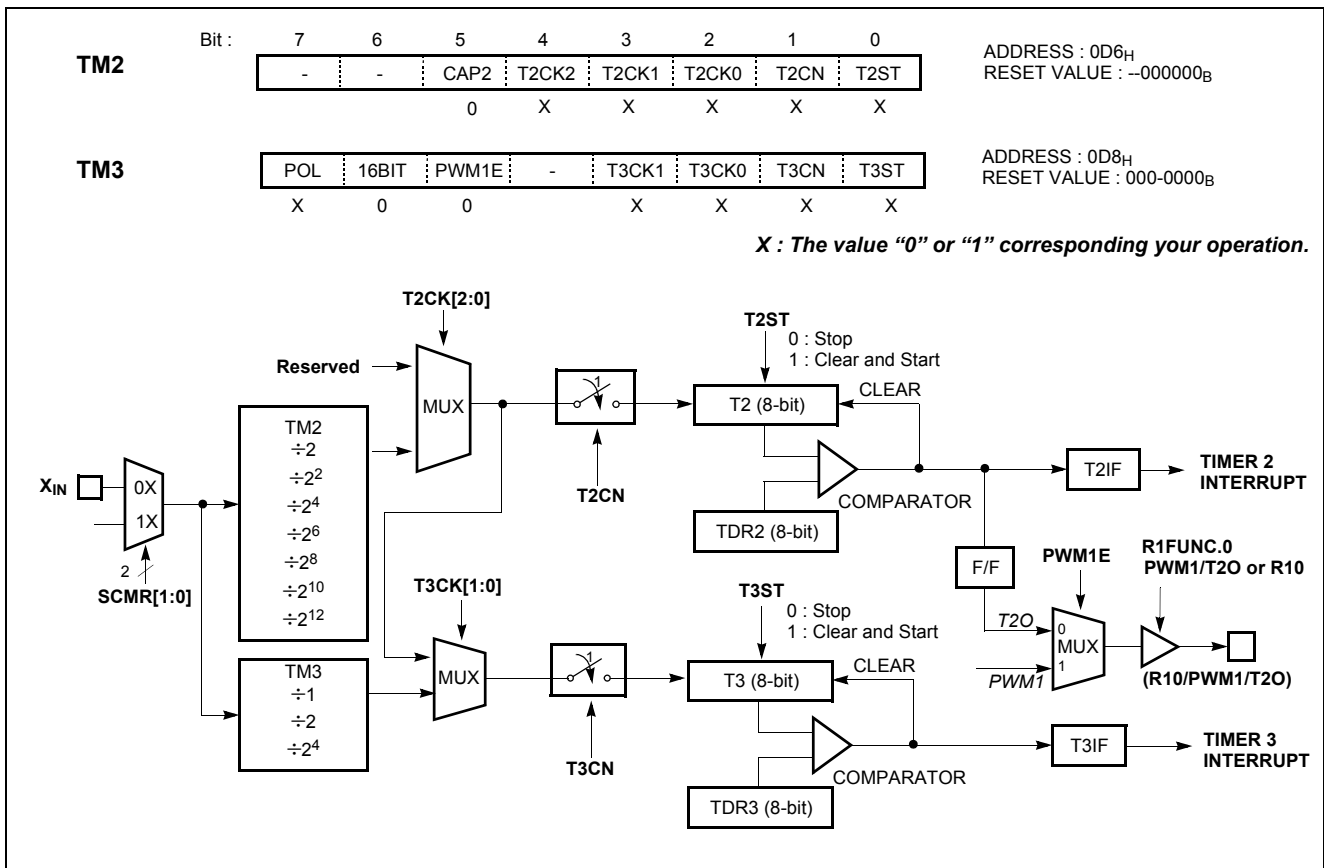

Figure 12-5 Block Diagram of Timer 2,3

These timers have each 8-bit count register and data register. The count register is increased by every internal or external clock input. The internal clock has a prescaler divide ratio option of 2, 4, 8, 32, 128, 512, 2048 (selected by control bits TxCK2, TxCK1 and TxCK0 of register TM0(2)) and 1, 2, 8 (selected by control bits TxCK1 and TxCK0 of register TM1(3)).

In the Timer, timer register Tx increases from 00H until it matches TxDR and then reset to 00H. If the value of Tx is equal with TxDR, Timer x interrupt is occurred (latched in TxIF bit). TxDR and T0 register are in same address, so this register is read from T0 and written to TDR0.

In counter function, the counter is increased every 0-to 1 (rising edge) transition of EC0 pin. In order to use counter function, the bit R01 of the R0 Direction Register (R0IO) should be set to "0" and the bit EC0E of Port Selection Register PSR0 should set to "1". The Timer 0 can be used as a counter by pin EC0 input, but other timers can not used as an event counter.

Note: The contents of TDR0, TDR1, TDR2 and TDR3 must be initialized (by software) with the value between 1H and 0FFH, not 0H.

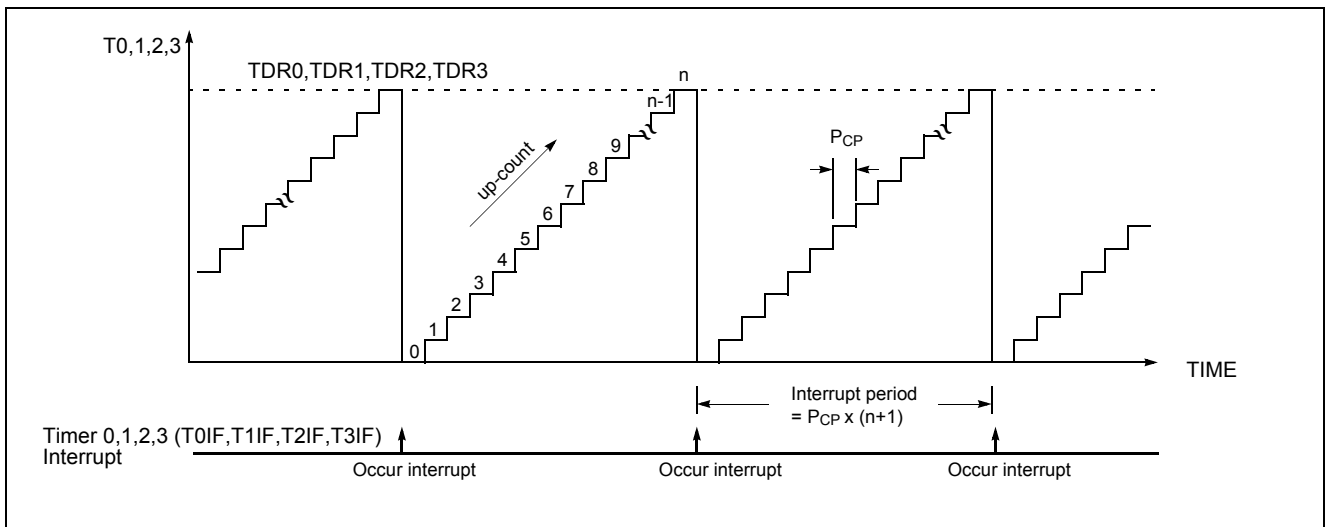

Figure 12-6 Counting Example of Timer Data Registers

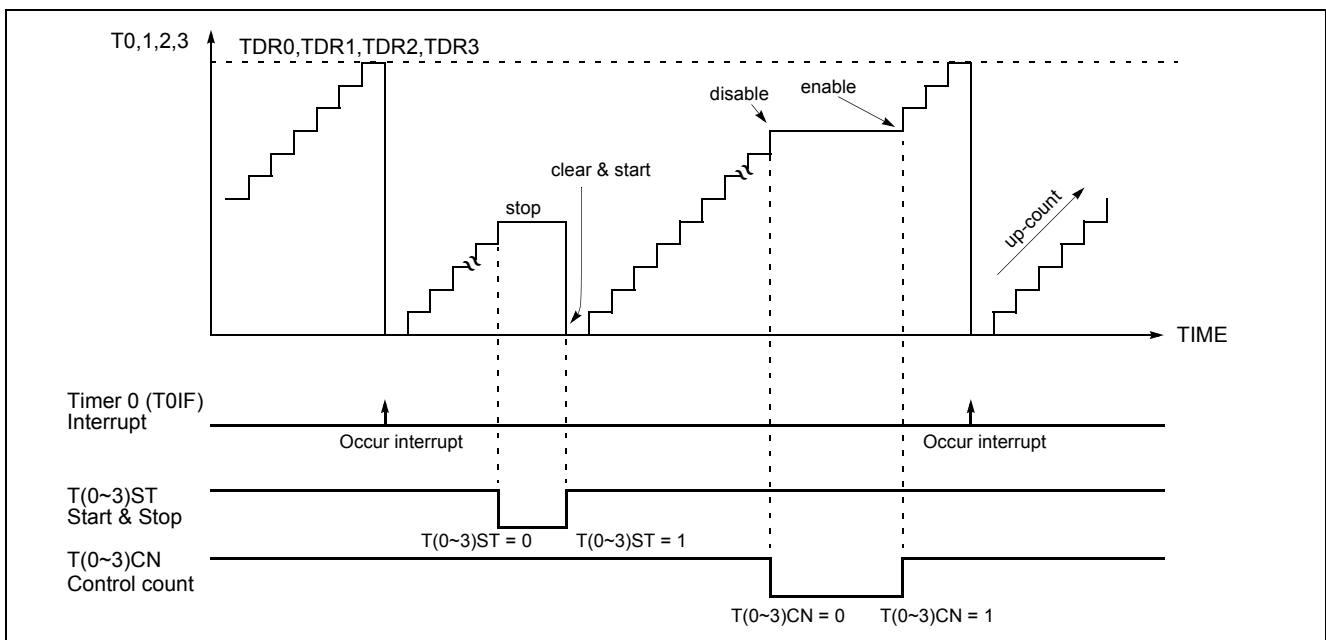

Figure 12-7 Timer Count Operation

12.2 16 Bit Timer/Counter Mode

The Timer register is running with 16 bits. A 16-bit timer/counter register T0, T1 are increased from 0000_H until it matches TDR0, TDR1 and then resets to 0000_H. The match output generates Timer 0 interrupt not Timer 1 interrupt.

The clock source of the Timer 0 is selected either internal or external clock by bit T0CK2, T0CK1 and T0CK0.

In 16-bit mode, the bits T1CK1, T1CK0 and 16BIT of TM1

should be set to “1” respectively.

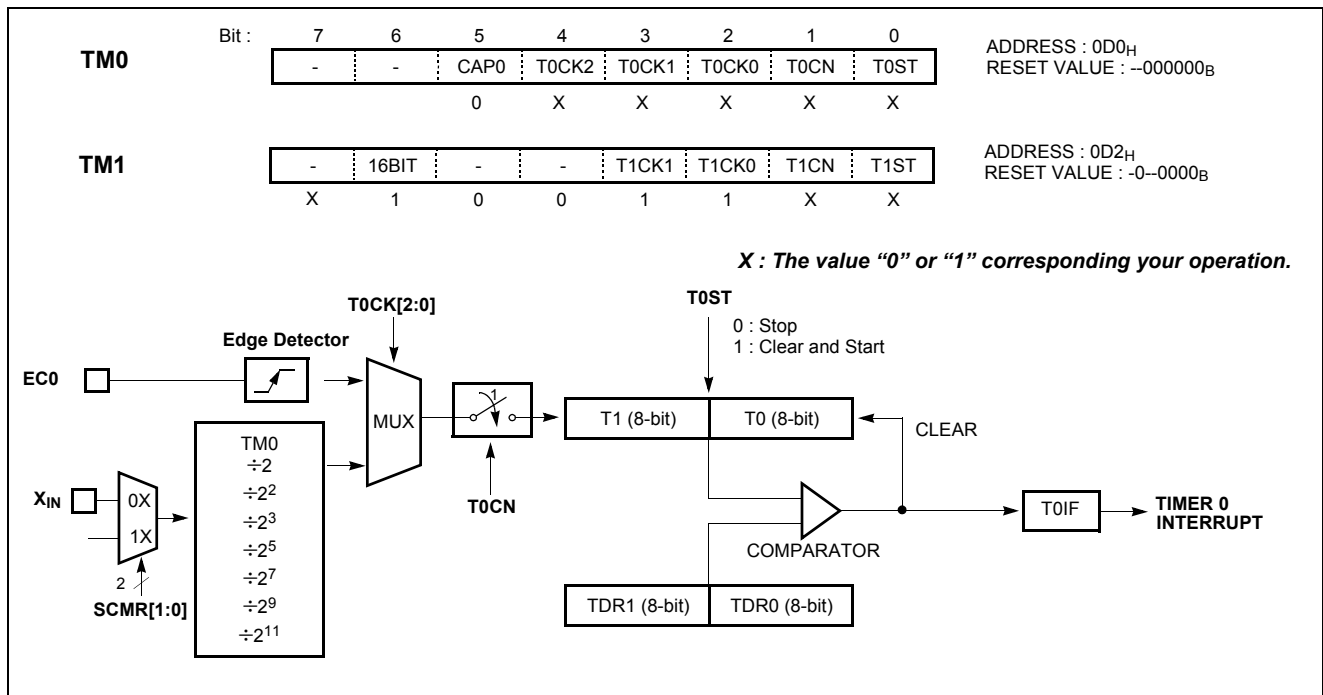

Figure 12-8 16-bit Timer / Counter Mode 0

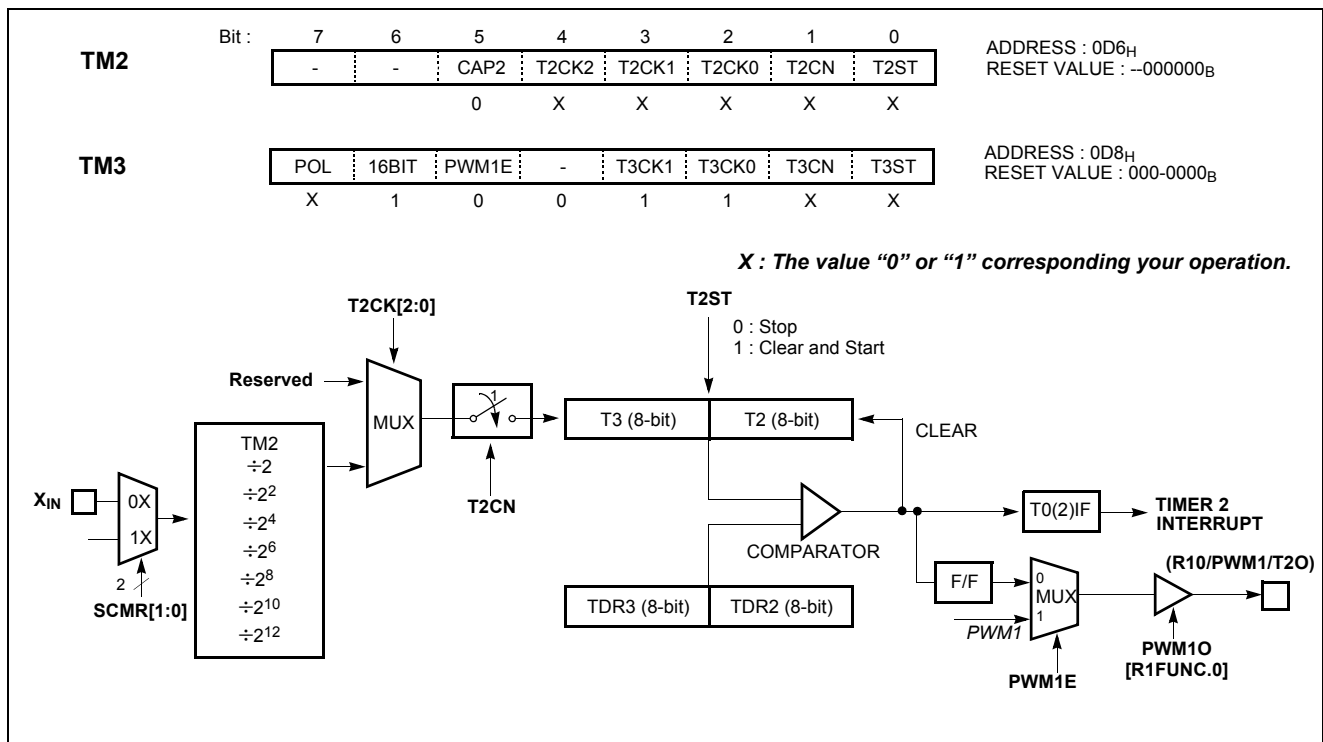

Figure 12-9 16-bit Timer / Counter Mode 2

12.3 8-Bit Capture Mode

The Timer 0 capture mode is set by bit CAP0 of timer mode register TM0 (bit CAPx of timer mode register TMx for Timer 1,2,3) as shown in Figure 12-10.

As mentioned above, not only Timer 0 but Timer 1,2,3 can also be used as a capture mode.

The Timer/Counter register is increased in response internal or external input. This counting function is same with normal timer mode, and Timer interrupt is generated when timer register T0 (T1,2,3) increases and matches TDR0 (TDR1,TDR2,TDR3).

This timer interrupt in capture mode is very useful when the pulse width of captured signal is more wider than the maximum period of Timer.

For example, in Figure 12-13, the pulse width of captured signal is wider than the timer data value (FF_H) over 2 times. When external interrupt is occurred, the captured value (13_H) is more little than wanted value. It can be obtained correct value by counting the number of timer over-

flow occurrence.

Timer/Counter still does the above, but with the added feature that a edge transition at external input INTx pin causes the current value in the Timer x register (T0,T1,T2,T3), to be captured into registers CDRx (x=0,1,2,3), respectively. After captured, Timer x register is cleared and restarts by hardware.

It has three transition modes: “falling edge”, “rising edge”, “both edge” which are selected by interrupt edge selection register IEDS (Refer to External interrupt section). In addition, the transition at INTx pin generate an interrupt.

Note: *The CDR0, TDR0 and T0 are in same address. In the capture mode, reading operation is to read the CDR0 and in timer mode, reading operation is read the T0. TDR0 is only for writing operation. The CDR1, T1 are in same address, the TDR1 is located in different address. In the capture mode, reading operation is to read the CDR1*

Figure 12-10 8-bit Capture Mode (Timer0, Timer1)

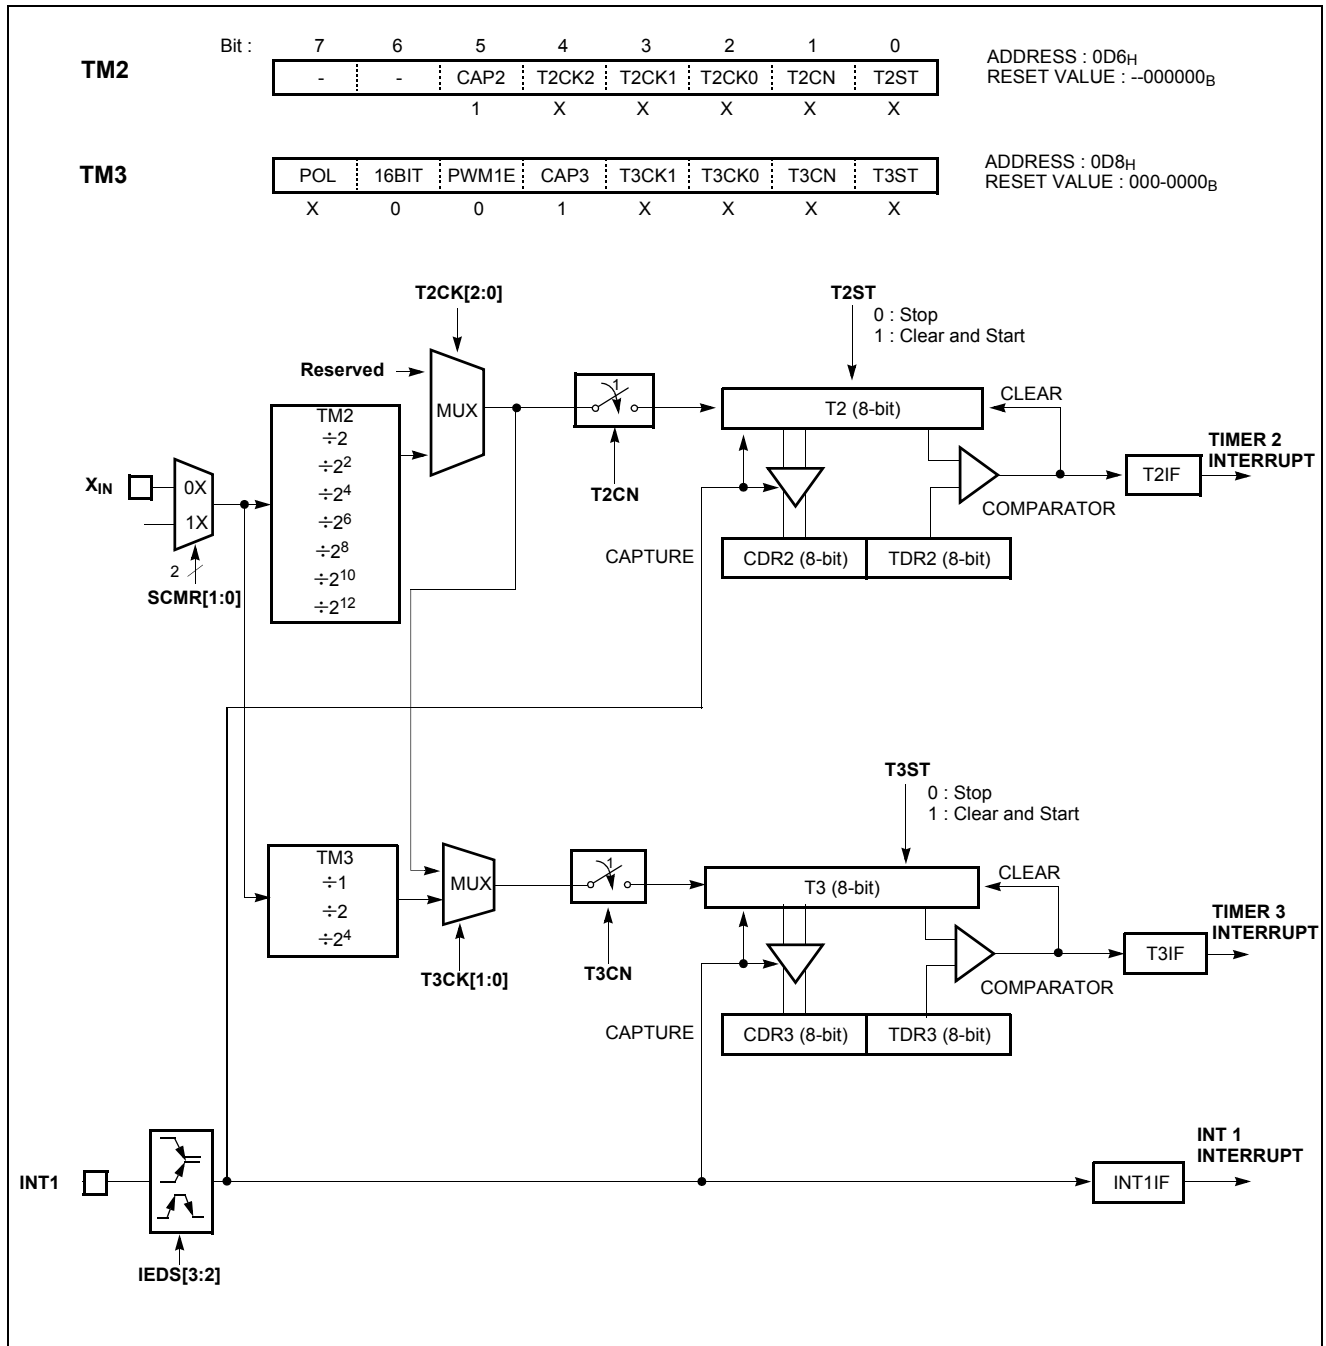

Figure 12-11 8-bit Capture Mode (Timer2, Timer3)

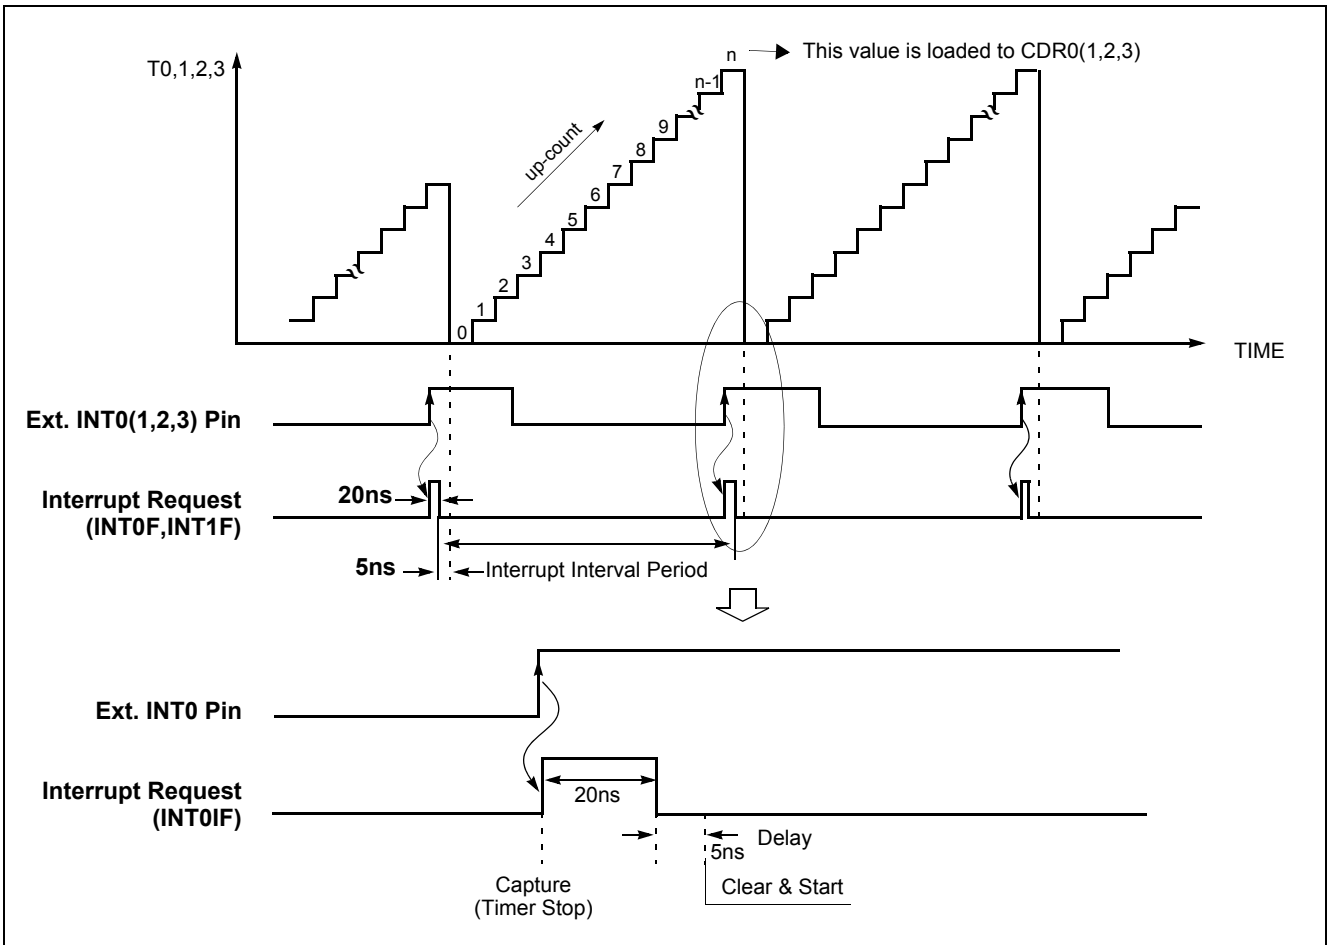

Figure 12-12 Input Capture Operation

Figure 12-13 Excess Timer Overflow in Capture Mode

12.4 16-bit Capture Mode

16-bit capture mode is the same as 8-bit capture, except that the Timer register is running with 16 bits.

In 16-bit mode, the bits TxCK1, TxCK0 and 16BIT of TM1, TM3 should be set to "1" respectively.

The clock source of the Timer 0,2 is selected either internal or external clock by bit TxCK2, TxCK1 and TxCK0.

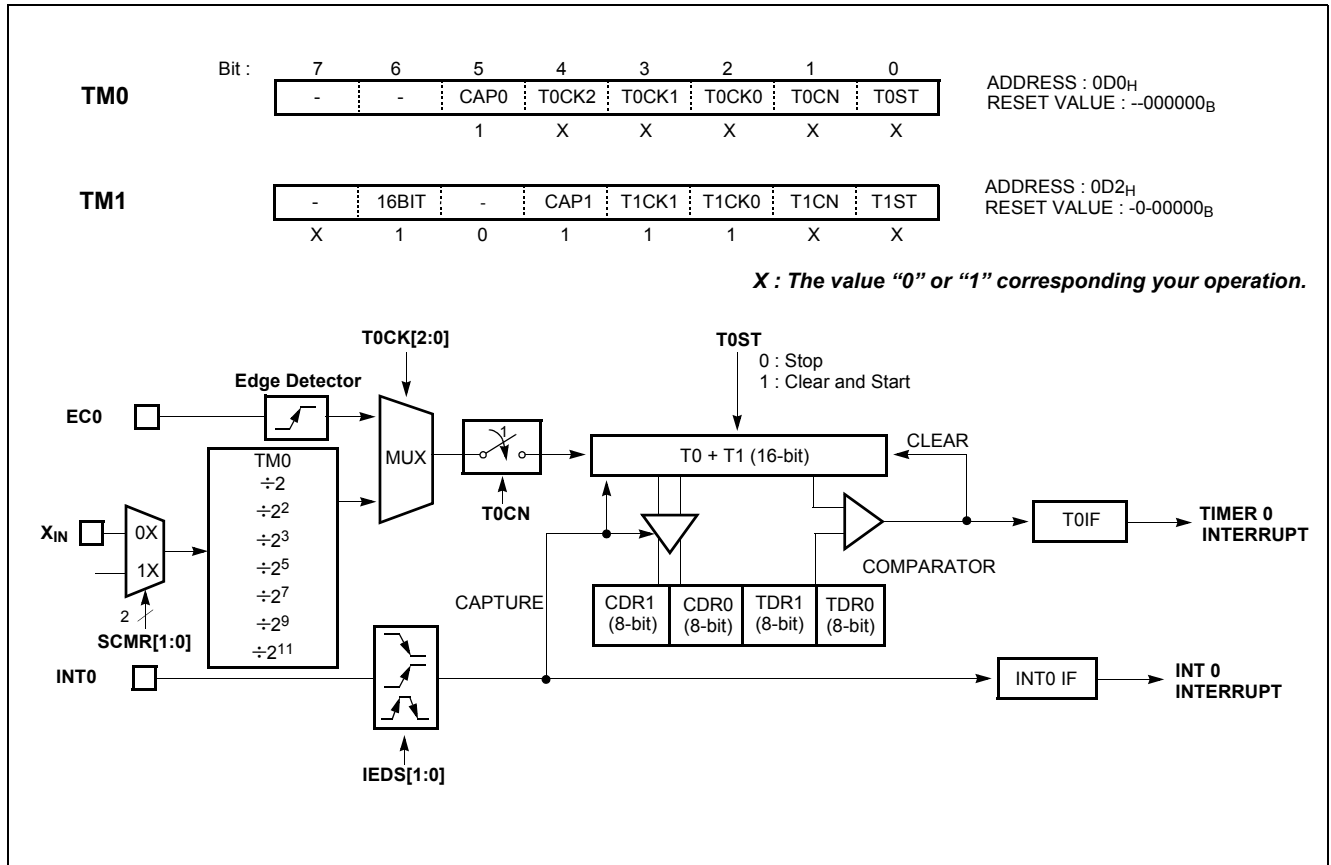

Figure 12-14 16-bit Capture Mode (Timer0,1)

Figure 12-15 16-bit Capture Mode (Timer2,3)

12.5 8-Bit (16-Bit) Compare Output Mode

The MC80F7708 have a function of Timer Compare Output. To pulse out, the timer match can go to port pin (R10) as shown in Figure 12-4 and Figure 12-8. Thus, pulse out is generated by the timer match. These operation is implemented to pin, R10/PWM1/T2O.

In this mode, the bit PWM10 of Port Mode Register R1FUNC should be set to “1”, and the bit PWM1E of Timer3 Mode Register (TM3) should be cleared to “0”.

12.6 PWM Mode

The MC80F7708 has one high speed PWM (Pulse Width Modulation) function which shared with Timer3. In PWM mode, the R10/PWM1 pins operate as a 10-bit resolution PWM output port. For this mode, the bit PWM10 of Port Mode Register (R1FUNC) and the bit PWM1E of timer3 mode register (TM3) should be set to “1” respectively.

The period of the PWM output is determined by the T3PPR (T3 PWM Period Register) and T3PWHR[3:2] (bit3, 2 of T3 PWM High Register) and the duty of the PWM output is determined by the T3PDR (T3 PWM Duty

In addition, 16-bit Compare output mode is available, also. This pin output the signal having a 50: 50 duty square wave, and output frequency is same as below equation

$$f_{COMP} = \frac{f_{XIN}}{2 \times PrescalerValue \times (TDR + 1)}$$

Register) and T3PWHR[1:0] (bit1, 0 of T3PWM High Register).

The user can use PWM data by writing the lower 8-bit period value to the T3PPR and the higher 2-bit period value to the T3PWHR[3:2]. And the duty value can be used with the T3PDR and the T3PWHR[1:0] in the same way.

The T3PDR is configured as a double buffering for glitch-less PWM output. In Figure 12-16, the duty data is transferred from the master to the slave when the period data matched to the counted value. (i.e. at the beginning of next

duty cycle).

The bit POL1 of TM3 decides the polarity of duty cycle.

The duty value can be changed when the PWM outputs. However the changed duty value is output after the current period is over. And it can be maintained the duty value at present output when changed only period value shown as Figure 12-18. As it were, the absolute duty time is not changed in varying frequency.

Note: If the user need to change mode from the Timer3 mode to the PWM mode, the Timer3 should be stopped firstly, and then set period and duty register value. If user writes register values and changes mode to PWM mode while Timer3 is in operation, the PWM data would be different from expected data in the beginning.

The relation of frequency and resolution is in inverse proportion. Table 12-2 shows the relation of PWM frequency vs. resolution.

$$PWM\ Period = [T3PWHR[3:2]T3PPR+1] \times Source\ Clock$$

$$PWM\ Duty = [T3PWHR[1:0]T3PDR+1] \times Source\ Clock$$

If it needed more higher frequency of PWM, it should be reduced resolution.

Note: If the duty value and the period value are same, the PWM output is determined by the bit POL1 (1: High, 0: Low). And if the duty value is set to "00_H", the PWM output is determined by the bit POL1(1: Low, 0: High). The period value must be same or more than the duty value, and 00_H cannot be used as the period value.

Resolution	Frequency		
	T3CK[1:0] =00 (250nS)	T3CK[1:0] =01 (500nS)	T3CK[1:0] =10 (2uS)
10-bit	3.9kHz	1.95kHz	0.49kHz
9-bit	7.8kHz	3.9kHz	0.98kHz
8-bit	15.6kHz	7.8kHz	1.95kHz
7-bit	31.2kHz	15.6kHz	3.90kHz

13. WATCH TIMER

The watch timer generates interrupt for watch operation. The watch timer consists of the clock selector, 21-bit binary counter and watch timer mode register. It is a multi-purpose timer. It is generally used for watch design.

The bit 0, 1, 2 of WTMR select the clock source of watch timer among sub-clock, $f_{MAIN} \div 2^8$, $f_{MAIN} \div 2^7$, f_{MAIN} or $f_{MAIN} \div 2$ of main-clock and f_{MAIN} of main-clock. The f_{MAIN} of main-clock is used usually for watch timer test, so generally it is not used for the clock source of watch timer. The $f_{MAIN} \div 2^7$ or $f_{MAIN} \div 2^8$ clock is used when the single clock system is organized. If $f_{MAIN} \div 2^8$ or $f_{MAIN} \div 2^7$ clock is used as watch timer clock source, when the CPU enters into stop mode, the main clock is stopped and then watch

timer is also stopped. If the sub-clock is used as the watch timer source clock, the watch timer count cannot be stopped. Therefore, the sub-clock does not stop and continues to oscillate even when the CPU is in the STOP mode. The timer counter consists of 21-bit binary counter and it can count to max 60 seconds at sub-clock.

The bit 3, 4 of WTMR select the interrupt request interval of watch timer among 2Hz, 4Hz, 16Hz and 1/64Hz.

Note: The Clock source of watch timer is also applied to LCD driver clock source. When selecting LCD driver clock source, the WTCK[2:0] should be set to appropriate value.

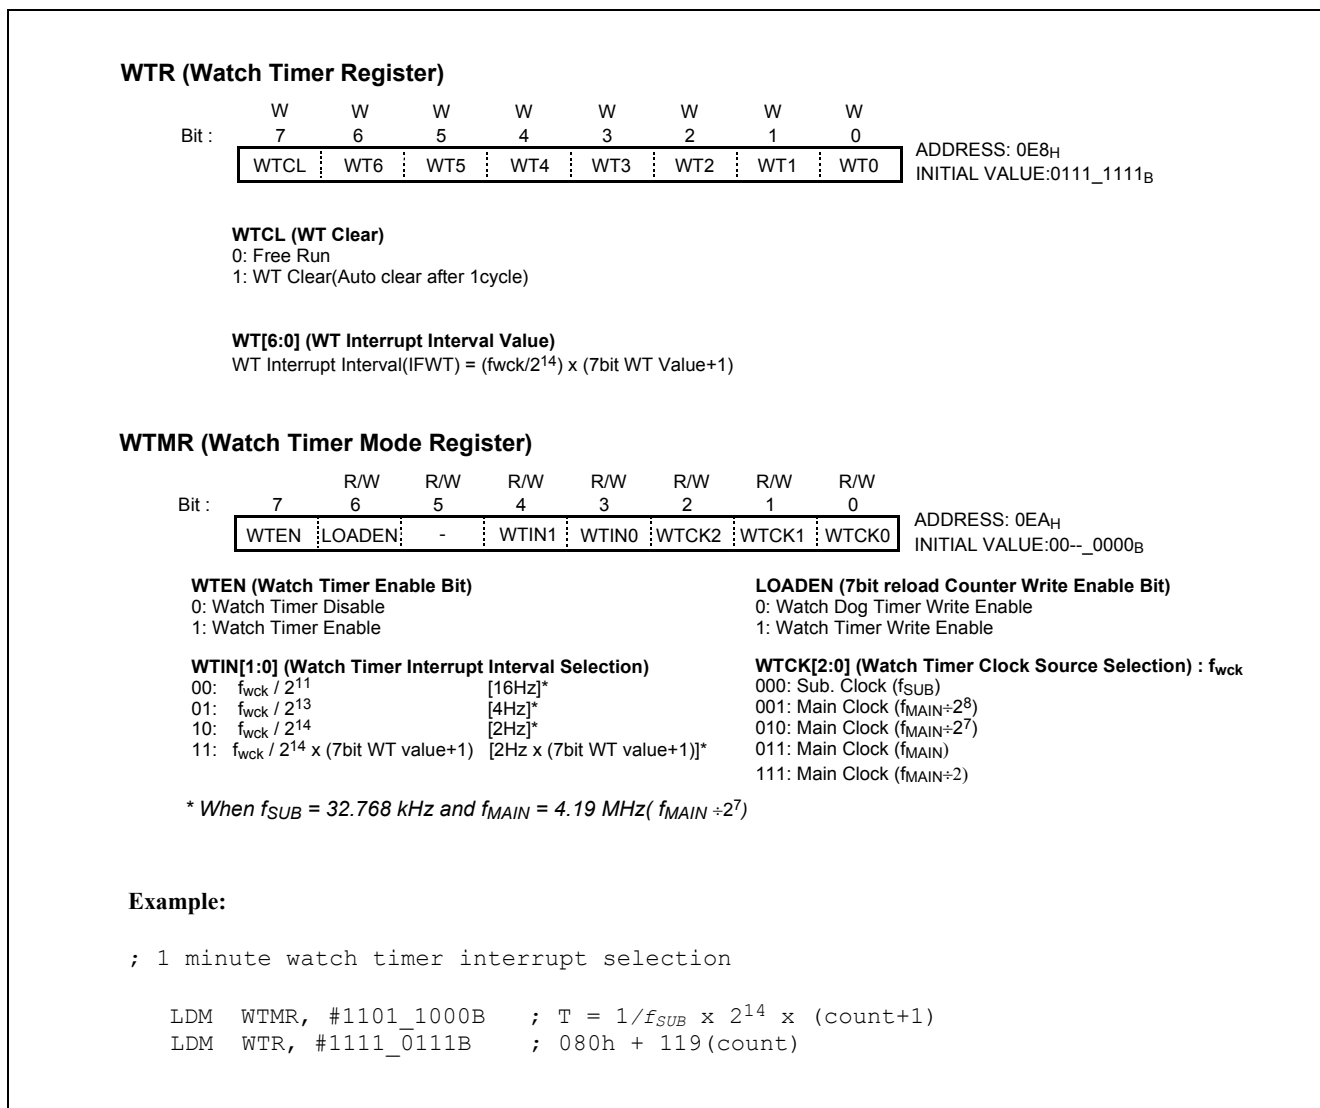

Figure 13-1 Watch Timer Mode Register

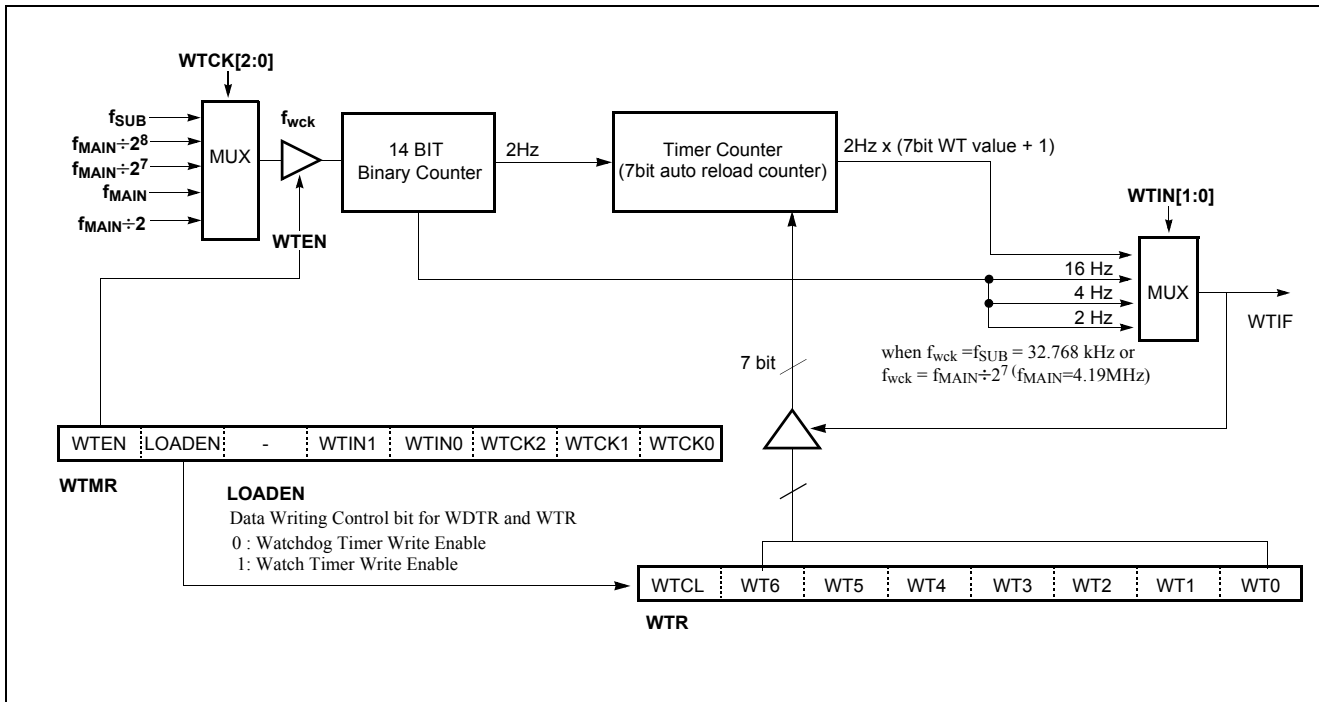

Figure 13-2 Watch Timer Block Diagram

Usage of Watch Timer in STOP Mode

When the system is off and the watch should be kept working, follow the steps below.

1. Set the clock source of watch timer to sub-clock.
2. Enters into STOP mode.
3. After released by watch timer interrupt, counts up timer and refreshes LCD Display. When performing count up and refresh the LCD, the CPU operates in main frequency mode.

4. Enters into STOP mode again.

5. Repeats 3 and 4.

When using STOP mode, if the watch timer interrupt interval is selected to 2Hz, the power consumption can be reduced considerably.

14. WATCH DOG TIMER

The watch dog timer (WDT) function is used for checking program malfunction due to external noise or other causes and return the operation to the normal contion.

The watchdog timer consists of 7-bit binary counter and the watchdog timer register(WDTR). The source clock of WDT is overflow of Basic Interval Timer. When the value of 7-bit binary counter is equal to the lower 7-bits of WDTR, the interrupt request flag is generated. This can be used as WDT interrupt or CPU reset signal in accordance with the bit WDTON. When WDTCL is set, 7-bit counter of WDT is reset. After one cycle, it is cleared by hardware.

When writing WDTR, the LOADEN bit of WTMR regis-

ter should be cleared to “0”.

Note: WDTR and WTR has same address 0E8h. The LOADEN bit is used to select WDTR or WTR. When LOADEN of watch timer mode register(WTMR) is set to “1”, WDTR can not be wrote and WTR is wrote. The LOADEN bit should be cleared to “0” when writing any value to WDTR.

Note: When using watch dog timer, don't write WDT[6:0] to “000000”.

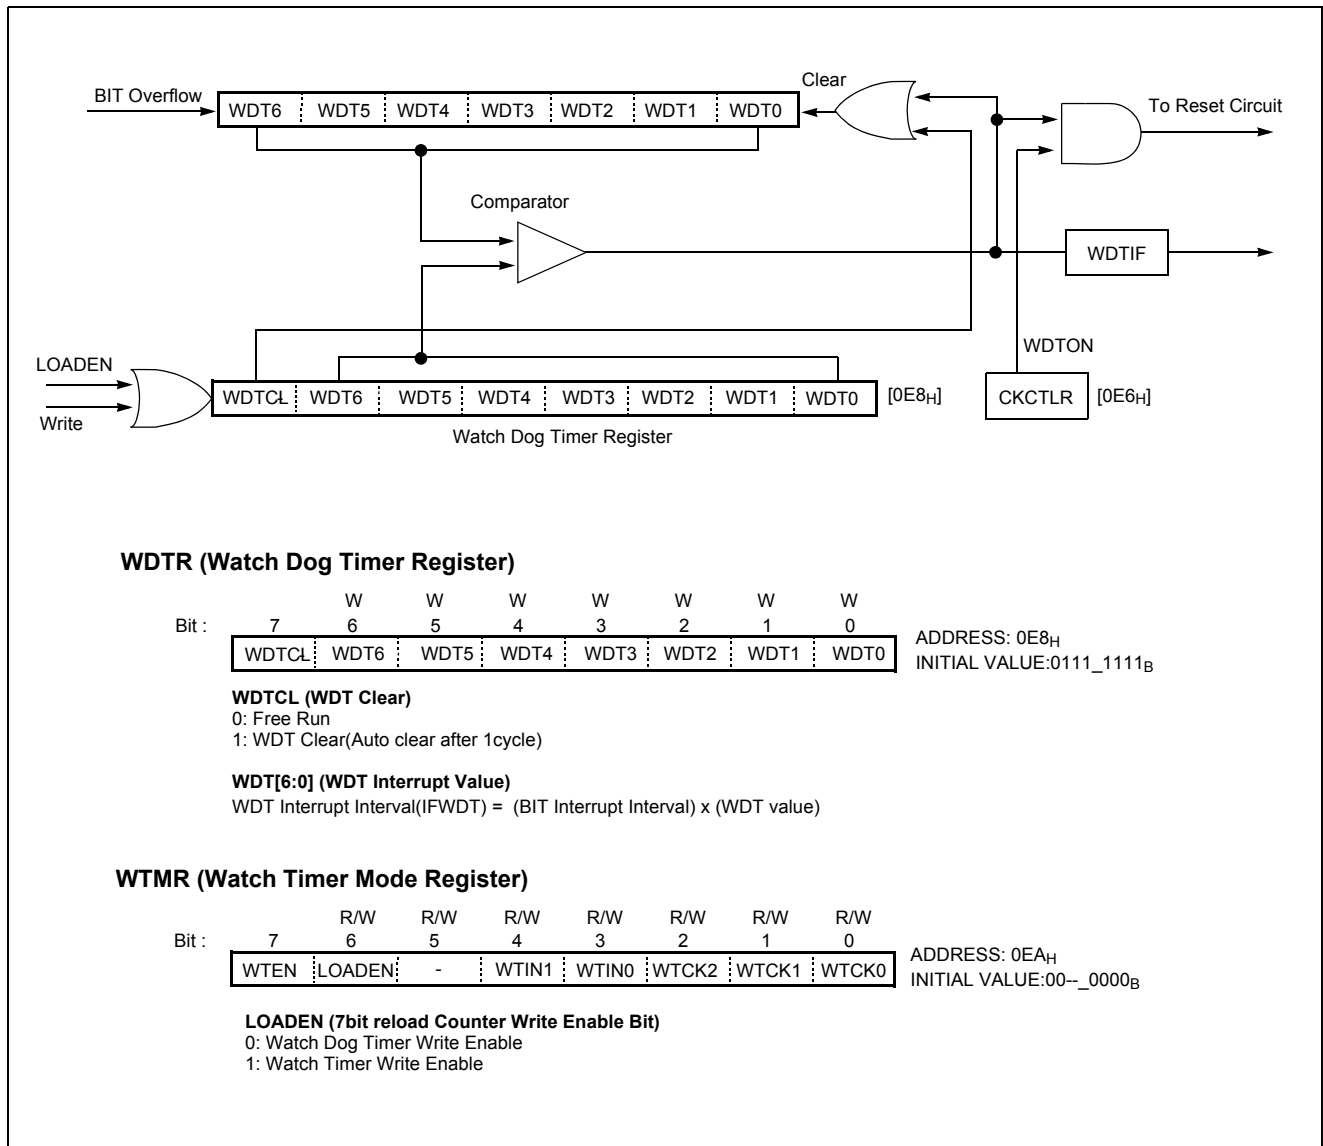

Figure 14-1 Block Diagram of Watch Dog Timer

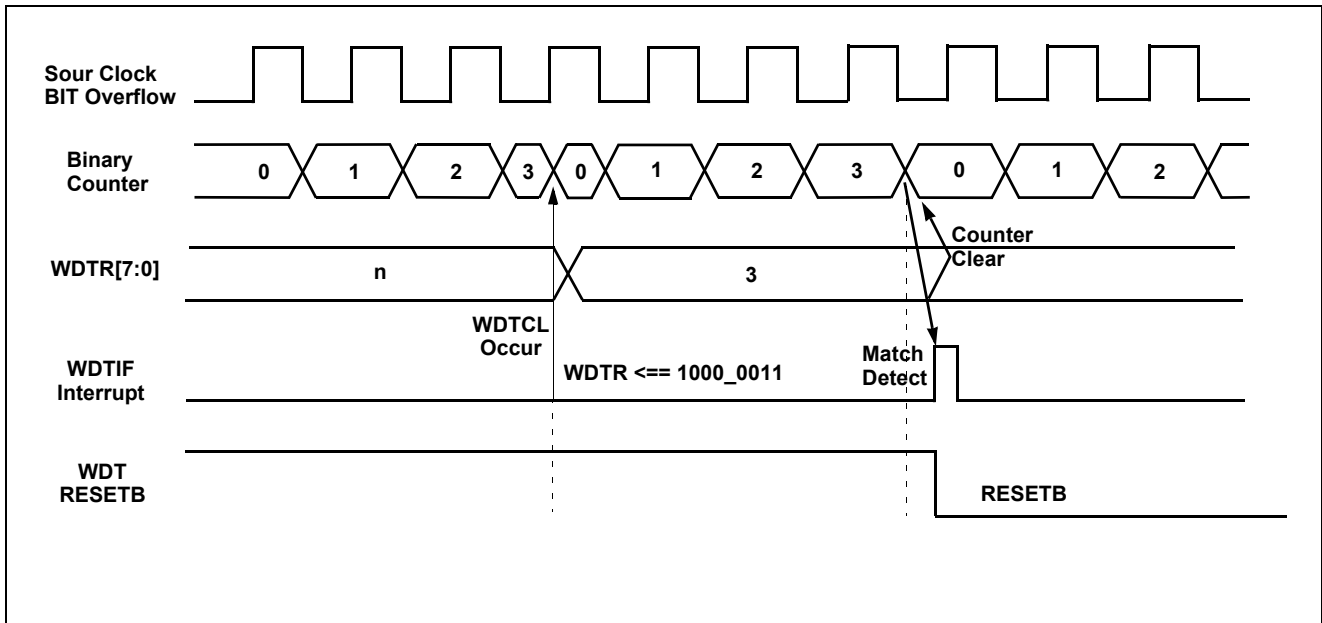

Figure 14-2 Watch Dog Timer Interrupt Time

15. ANALOG TO DIGITAL CONVERTER

The analog-to-digital(A/D) converter allows conversion of an analog input signal to an corresponding 10-bit digital value. The A/D module has six analog inputs, which are multiplexed into one sample and hold. The output of the sample and hold is the input of the converter, which generates the result via successive approximation. The analog supply voltage is connected to AV_{DD} of ladder resistance of A/D module.

The A/D module has three registers which are the control register ADCM and A/D result register ADCRH and ADCRL. The ADCRH[7:6] is also used as ADC clock source selection bits. The ADCM register, shown in Figure 15-2, controls the operation of the A/D converter module. The port pins can be configured as analog inputs or digital I/O. To use analog inputs, each port should be assigned analog input port by setting R2IO direction register as input mode and setting ADS[3:0] to select the corresponding channel.

The self bias check reference provides fixed voltage (typical 1.185V, tolerance to be defined), which can be the input of ADC when setting ADS[3:0] to "1111b". This feature can be used to check the voltage of VDD pin. The BIR_ENB and AD_REFB of BIRR register should be set to "0" for using self bias check reference.

The processing of conversion is start when the start bit ADST is set to "1". After one cycle, it is cleared by hardware. The register ADCRH and ADCRL contain the result (10bit) of the A/D conversion. If the ADC is set to 8-bit mode (ADC8 bit of ADCRH is "1b"), ADCRL contains the result of the A/D conversion. When the conversion is completed, the result is loaded into the ADCR, the A/D conversion status bit ADF is set to "1", and the A/D interrupt flag ADIF is set. The block diagram of the A/D module is shown in Figure 15-1. The A/D status bit ADF is automatically set when A/D conversion is completed, cleared when A/D conversion is in process. The conversion needs 13 clock period of ADC clock (f_{PS}). It is recommended to use ADC clock of at least 1us period.

Note: The ADC value of self bias check reference(V_{bias_ref}) is can be used to check the VDD voltage. When V_{bias_ref} is 1.185V and VDD is 5.12V, the ADC value is "0EDh". If VDD is changed and ADC value is "13Ch", the VDD voltage is 3.84V. the ADC value is changed to "13Ch". The VDD voltage can be calculated by following formula.

$$VDD \text{ voltage} = V_{bias_ref} \times 1024 \div \text{ADC Value}$$

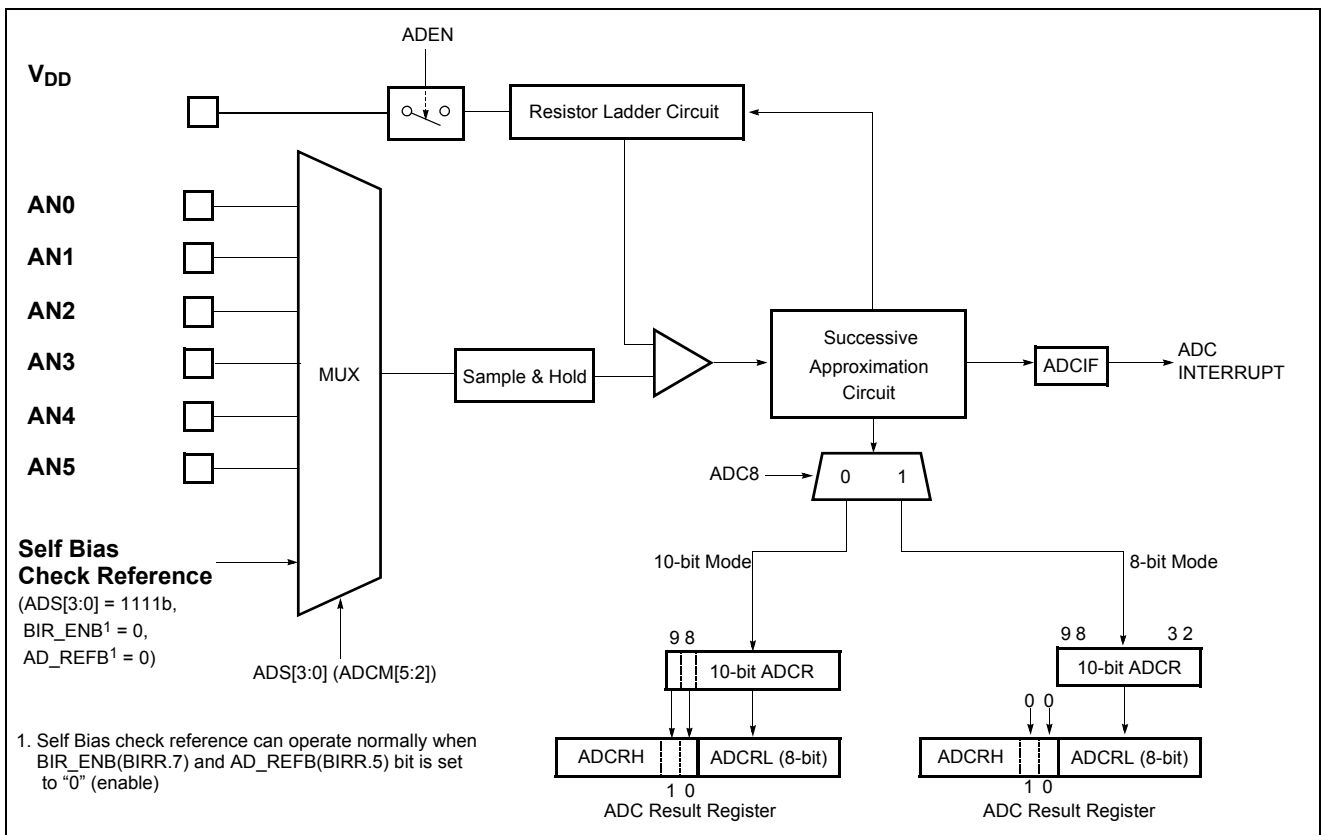

Figure 15-1 A/D Converter Block Diagram & Registers

Figure 15-2 A/D Converter Mode & Result Registers

Figure 15-3 A/D Converter Operation Flow

A/D Converter Cautions

(1) Input range of AN0 to AN5

The input voltages of AN0 to AN7 should be within the specification range. In particular, if a voltage above AV_{DD} or below V_{SS} is input (even if within the absolute maximum rating range), the conversion value for that channel can not be determined. The conversion values of the other channels may also be affected.

(2) Noise counter measures

In order to maintain 8-bit resolution, any attention must be paid to noise on pins AV_{DD} and AN0 to AN7. Since the ef-

fect increases in proportion to the output impedance of the analog input source, it is recommended that a capacitor is connected externally as shown below in order to reduce noise.

Figure 15-4 Analog Input Pin Connecting Capacitor

(3) Pins AN0/R20 to AN5/R25

The analog input pins AN0 to AN5 also function as input/output port (PORT R2) pins. When A/D conversion is performed with any of pins AN0 to AN57 selected, be sure not to execute a PORT input instruction while conversion is in progress, as this may reduce the conversion resolution.

Also, if digital pulses are applied to a pin adjacent to the pin in the process of A/D conversion, the expected A/D conversion value may not be obtainable due to coupling noise. Therefore, avoid applying pulses to pins adjacent to the pin undergoing A/D conversion.

(4) AV_{DD} pin input impedance

A series resistor string of approximately $10K\Omega$ is connected between the AV_{DD} pin and the V_{SS} pin.

Therefore, if the output impedance of the reference voltage source is high, this will result in parallel connection to the series resistor string between the AV_{DD} pin and the V_{SS} pin, and there will be a large reference voltage error.

16. BUZZER OUTPUT FUNCTION

The buzzer driver consists of 6-bit binary counter, the buzzer driver register BUZR and the clock selector. It generates square-wave which is very wide range frequency (500 Hz~125 kHz at $f_{MAIN} = 4\text{MHz}$) by user programmable counter.

Pin R04/BUZO is assigned for output port of Buzzer driver by setting the bit BUZO of R0 Function Register(R0FUNC) to "1".

The 6-bit buzzer counter is cleared and start the counting by writing signal to the register BUZR. It is increased from 00_H until it matches with BUR[5:0].

Also, it is cleared by counter overflow and count up to output the square wave pulse of duty 50%.

The bit 0 to 5 of BUZR determines output frequency for

buzzer driving. BUZR[5:0] is initialized to 3F_H after reset. Note that BUZR is a write-only register. Frequency calculation is following as shown below.

$$f_{BUZ} = \frac{f_{XIN}}{2 \times DivideRatio \times (BUZR[5:0] + 1)}$$

The bits BUCK1, BUCK0 of BUZR select the source clock from prescaler output.

- f_{BUZ} : Buzzer frequency
- f_{XIN} : Oscillator frequency
- Divide Ratio: Prescaler divide ratio by BUCK[1:0]
- BUZR[5:0]: Lower 6-bit value of BUZR. Buzzer control data

Table 16-1 Buzzer Output Frequency

17. INTERRUPTS

The MC80F7708 interrupt circuits consist of Interrupt enable register (IENH, IENM, IENL), Interrupt request flag register (IRQH, IRQM, IRQL), Interrupt flag register (INTFH, INTFL), Interrupt Edge Selection Register (IEDS), priority circuit and Master enable flag (“I” flag of PSW). The interrupts are controlled by the interrupt master enable flag I-flag (bit 2 of PSW), the interrupt enable register and the interrupt request flag register except Power-on reset and software BRK interrupt. The configuration of interrupt circuit is shown in Figure 17-1 and interrupt priority is shown in Table 17-1 .

Table 17-1 Vector Table

Reset/Interrupt	Symbol	Priority	Vector Addr.
Hardware Reset	RESET	0	FFFEH
External Int. 0	INTR0	1	FFFAH
External Int. 1	INTR1	2	FFF8H
External Int. 2	INTR2	3	FFF6H
External Int. 3	INTR3	4	FFF4H
UART_RX0	RX0	5	FFF2H
UART_TX0	TX0	6	FFF2H
Timer 0 Int.	T0	7	FFEEH
Timer 1 Int.	T1	8	FFECH
Timer 2 Int.	T2	9	FFEAH
Timer 3 Int.	T3	10	FFE8H
A/D Int.	ADC	11	FFE4H
BIT Int.	BIT	12	FFE2H
Watch Dog timer int.	WDT	13	FFE0H
Watch timer int.	WT	14	FFE0H

Each bit of interrupt request flag registers (IRQH, IRQM, IRQL) in Figure 17-1 is set when corresponding interrupt condition is met. The interrupt request flags that actually generate external interrupts are bit INT0F, INT1F and INT2F in Register IRQH and INT3F in Register IRQL. The External Interrupts INT0, INT1, INT2 and INT3 can each be transition-activated (1-to-0, 0-to-1 and both transition). The RX0 and TX0 of UART0 Interrupts are generated by RX0IF and TX0IF which are set by finishing the reception and transmission of data.

The Timer 0,1,2 and Timer 3 Interrupts are generated by T0IF, T1IF, T2IF and T3IF, which are set by a match in their respective timer/counter register. The AD converter

Interrupt is generated by ADCIF which is set by finishing the analog to digital conversion.

The Basic Interval Timer Interrupt is generated by BITIF which is set by overflow of the Basic Interval Timer Register (BITR). The Watch dog Interrupt is generated by WDTIF which set by a match in Watch dog timer register (when the bit WDTON is set to “0”). The Watch Timer Interrupt is generated by WTIF which is set periodically according to the established time interval.

When an interrupt is generated, the bit of interrupt request flag register (IRQH, IRQM, IRQL) that generated it may not cleared itself during interrupt acceptance processing. After interrupt acceptance, it should be cleared in interrupt service routine.

Each bit of Interrupt flag register (INTFH, INTFL) is set when corresponding interrupt flag bit as well as interrupt enable bit are set. The bits of interrupt flag register are never cleared by the hardware although the service routine is vectored to. Therefore, the interrupt flag register can be used to distinguish a right interrupt source from two available ones in a vector address. For example, RX0 and TX0 which have the same vector address (FFF2_H) may be distinguished by INTFH register.

Interrupt enable registers are shown in Figure 17-2. These registers are composed of interrupt enable bits of each interrupt source, these bits determine whether an interrupt will be accepted or not. When enable bit is “0”, a corresponding interrupt source is prohibited. Note that PSW contains also a master enable bit, I-flag, which disables all interrupts at once. When an interrupt is occurred, the I-flag is cleared and disable any further interrupt, the return address and PSW are pushed into the stack and the PC is vectored to.

In an interrupt service routine, any other interrupt may be serviced. The source(s) of these interrupts can be determined by polling the interrupt request flag bits. Then, the interrupt request flag bit(s) must be cleared by software before re-enabling interrupts to avoid recursive interrupts. The Interrupt Request flags are able to be read and written.

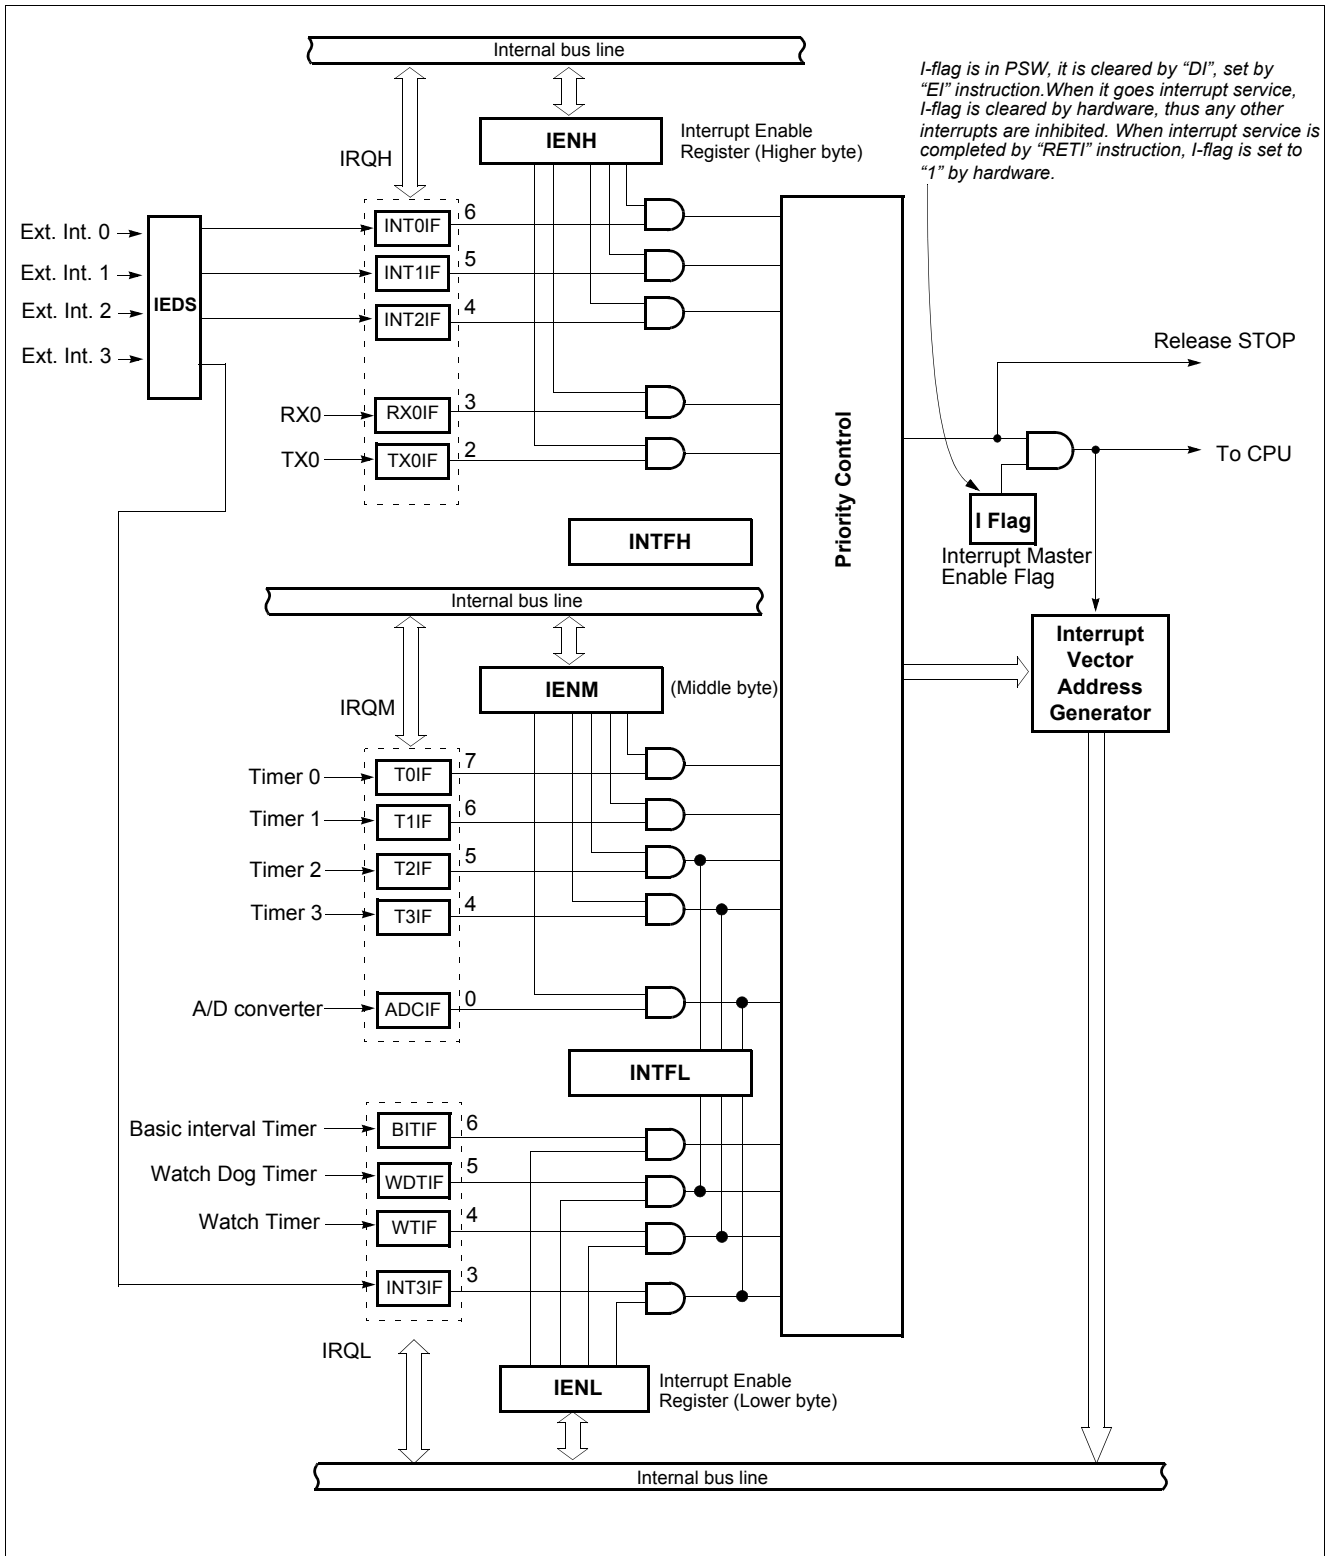

Figure 17-1 Block Diagram of Interrupt

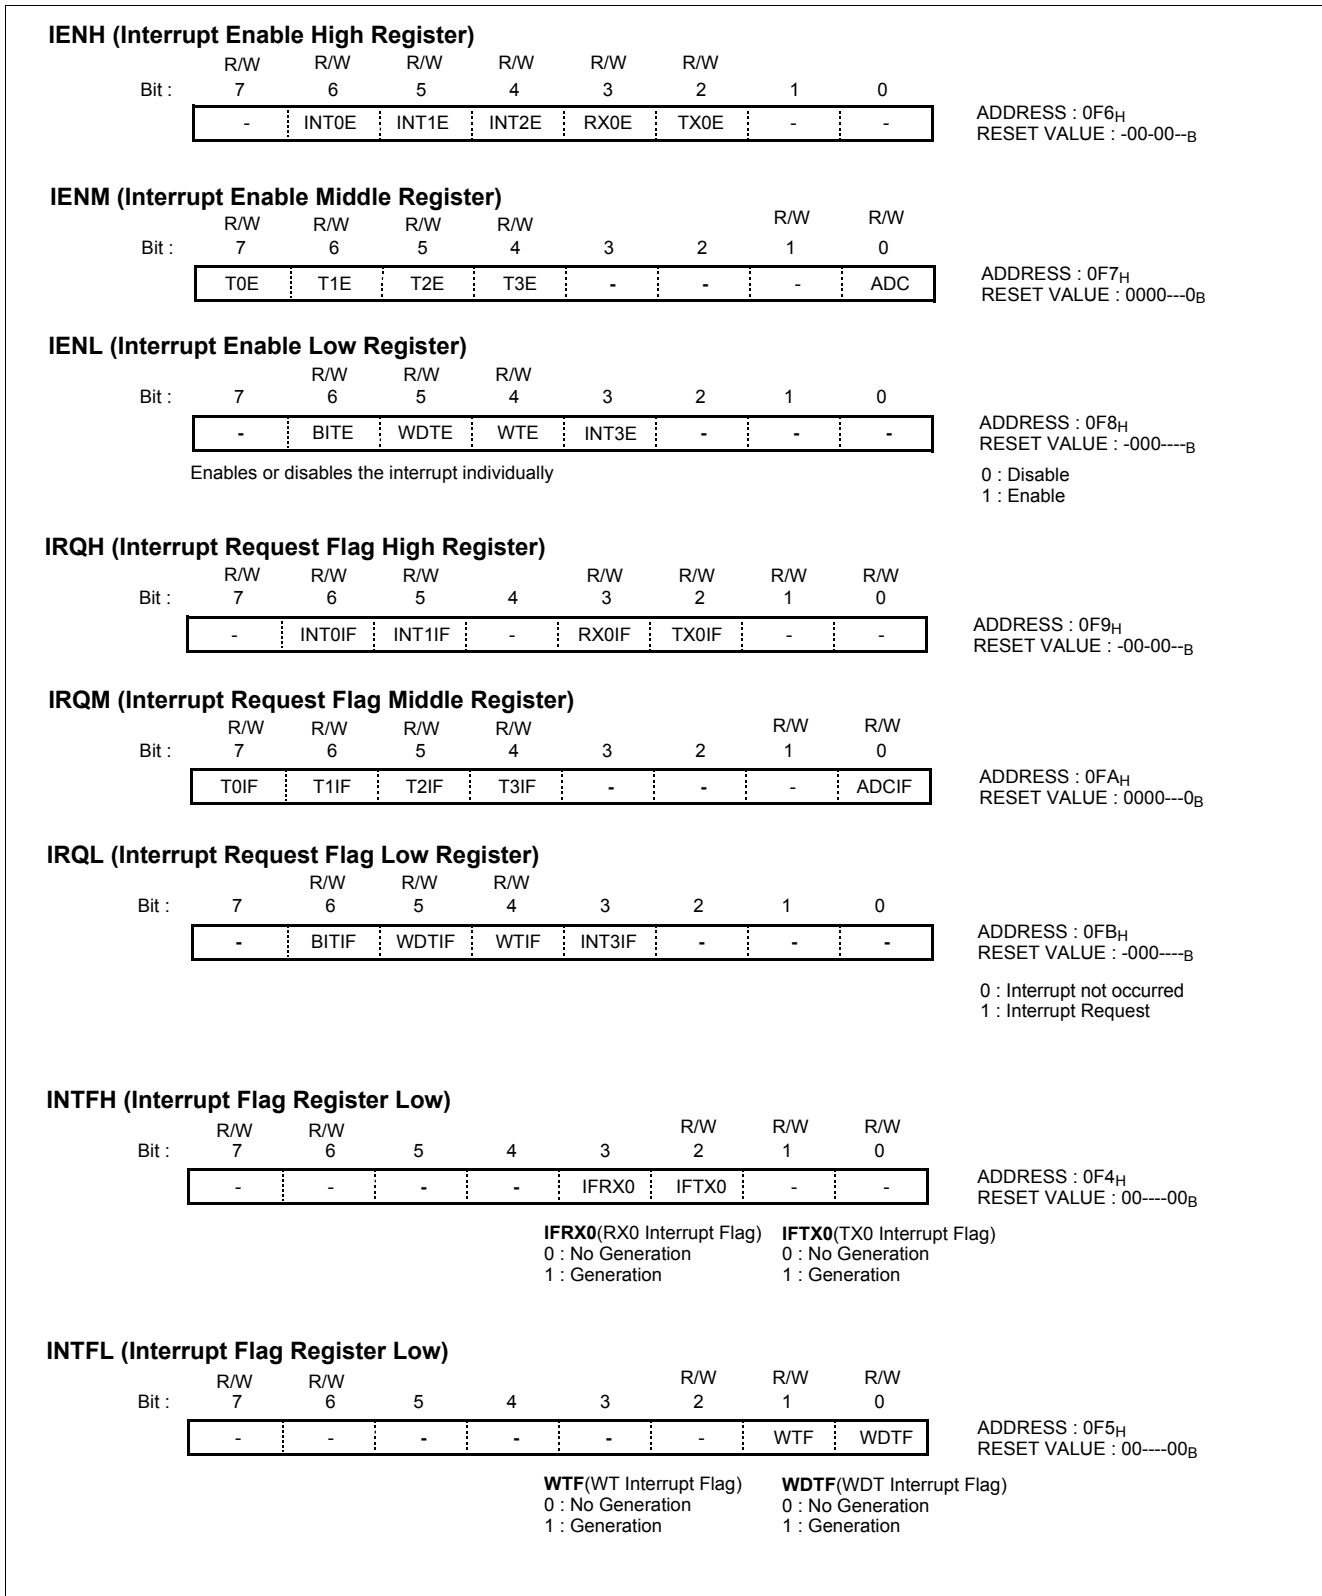

Figure 17-2 Interrupt Enable Registers and Interrupt Request Registers

17.1 Interrupt Sequence

An interrupt request is held until the interrupt is accepted or the interrupt latch is cleared to “0” by a reset or an instruction. Interrupt acceptance sequence requires $8 f_{OSC}$ ($2 \mu s$ at $f_{MAIN}=4MHz$) after the completion of the current instruction execution. The interrupt service task is terminated upon execution of an interrupt return instruction [RETI].

Interrupt acceptance

1. The interrupt master enable flag (I-flag) is cleared to “0” to temporarily disable the acceptance of any following maskable interrupts. When a non-maskable interrupt is accepted, the acceptance of any following interrupts is temporarily disabled.

2. Interrupt request flag for the interrupt source accepted is cleared to “0”.
3. The contents of the program counter (return address) and the program status word are saved (pushed) onto the stack area. The stack pointer decreases 3 times.
4. The entry address of the interrupt service program is read from the vector table address and the entry address is loaded to the program counter.
5. The instruction stored at the entry address of the interrupt service program is executed.

Figure 17-3 Timing chart of Interrupt Acceptance and Interrupt Return Instruction

Correspondence between vector table address for BIT interrupt and the entry address of the interrupt service program.

An interrupt request is not accepted until the I-flag is set to “1” even if a requested interrupt has higher priority than that of the current interrupt being serviced.

When nested interrupt service is required, the I-flag should be set to “1” by “EI” instruction in the interrupt service program. In this case, acceptable interrupt sources are selectively enabled by the individual interrupt enable flags.

Saving/Restoring General-purpose Register

During interrupt acceptance processing, the program counter and the program status word are automatically saved on the stack, but accumulator and other registers are not saved itself. If necessary, these registers should be saved by the software. Also, when multiple interrupt services are nested, it is necessary to avoid using the same data memory area for saving registers.

The following method is used to save/restore the general-purpose registers.

Example: Register saving

```
INTxx:  PUSH   A      ;SAVE ACC.
        PUSH   X      ;SAVE X REG.
        PUSH   Y      ;SAVE Y REG.
        [interrupt processing]
        POP    Y      ;RESTORE Y REG.
        POP    X      ;RESTORE X REG.
        POP    A      ;RESTORE ACC.
        RETI          ;RETURN
```

General-purpose registers are saved or restored by using push and pop instructions.

17.2 BRK Interrupt

Software interrupt can be invoked by BRK instruction, which has the lowest priority order.

Interrupt vector address of BRK is shared with the vector of TCALL 0 (Refer to Program Memory Section). When BRK interrupt is generated, B-flag of PSW is set to distinguish BRK from TCALL 0.

Each processing step is determined by B-flag as shown in Figure 17-4.

Figure 17-4 Execution of BRK/TCALL0

17.3 Multi Interrupt

If two requests of different priority levels are received simultaneously, the request of higher priority level is serviced. If requests of the interrupt are received at the same time simultaneously, an internal polling sequence determines by hardware which request is serviced.

However, multiple processing through software for special features is possible. Generally when an interrupt is accepted, the I-flag is cleared to disable any further interrupt. But as user sets I-flag in interrupt routine, some further interrupt can be serviced even if certain interrupt is in progress.

Example: Even though Timer1 interrupt is in progress, INTO interrupt serviced without any suspend.

```
TIMER1:  PUSH   A
         PUSH   X
         PUSH   Y
```

```
LDM   IENH, #40H ; Enable INTO only
LDM   IENM, #0   ; Disable other
LDM   IENL, #0   ; Disable other
EI    ; Enable Interrupt
:
:
:
:
LDM   IENH, #0FFH ; Enable all interrupts
LDM   IENM, #0FFH
LDM   IENL, #0F0H
POP   Y
POP   X
POP   A
RETI
```

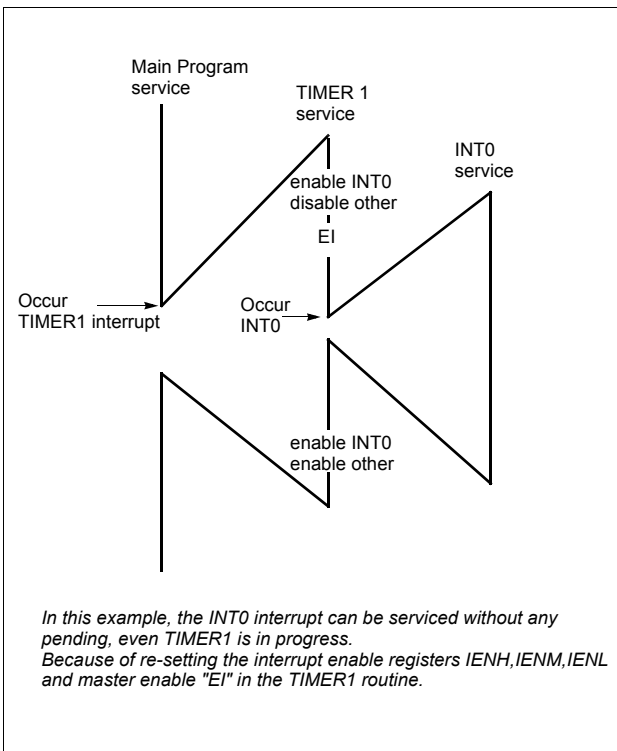

Figure 17-5 Execution of Multi Interrupt

17.4 External Interrupt

The external interrupt on INT0, INT1, INT2 and INT3 pins are edge triggered depending on the edge selection register IEDS (address 0FC_H) as shown in Figure 17-6.

The edge detection of external interrupt has three transition activated mode: rising edge, falling edge, and both edge.

Figure 17-6 External Interrupt Block Diagram

```

Response Time

The INT0, INT1, INT2 and INT3 edge are latched into INT0F, INT1F, INT2F and INT3F at every machine cycle. The values are not actually polled by the circuitry until the next machine cycle. If a request is active and conditions are right for it to be acknowledged, a hardware subroutine call to the requested service routine will be the next instruction to be executed. The DIV itself takes twelve cycles. Thus, a maximum of twelve complete machine cycles elapse between activation of an external interrupt request and the beginning of execution of the first instruction of the service routine.

Interrupt response timings are shown in Figure 17-7.

Figure 17-7 Interrupt Response Timing Diagram

18. LCD DRIVER

The MC80F7708 has the circuit that directly drives the liquid crystal display (LCD) and its control circuit. The segment/common driver directly drives the LCD panel, and the LCD controller generates the segment/common signals according to the RAM which stores display data. VCL3 ~ VCL0 voltage are made by the internal bias resistor circuit.

The MC80F7708 has the segment output port 16 pins (SEG0 ~ SEG15) and Common output port 8 pins (COM0 ~ COM7). If the LCDD0 bit of LCR is set to "1", COM4 ~ COM7 is used as SEG19 ~ SEG16.

The Figure 18-1 shows the configuration of the LCD driver.

Figure 18-1 LCD Driver Block Diagram

18.1 Control of LCD Driver Circuit

The LCD driver is controlled by the LCD Control Register (LCR). The LCR[1:0] determines the frequency of COM signal scanning of each segment output. RESET clears the LCD control register LCR values to logic zero. The LCD SEG or COM ports are selected by setting corresponding

bits of R5PSR, R6PSR or R7PSR to “0”.

The LCD display can continue to operate during SLEEP and STOP modes if sub-frequency clock is used as LCD clock source.

Figure 18-2 LCD Control Register

Note: If the SCKD is set to "1", the SXIN and SXOUT pin is used as normal I/O pin R45, R46.

Note: When the Sub clock is used as internal bias source clock, stabilization time is needed. Normally, the stabilization time is need more than 500ms.

Note: When selecting Sub clock as the LCD clock source, the WTCK[2:0] bit of WTMR(Watch Timer Mode Register) should be set to "000" as well as SCKD bit of LCR be set to "0".

Note: Bit 6, Bit 4, Bit 3 of LCR should be set to "1", "0", "1" respectively.

Selecting Frame Frequency

Frame frequency is set to the base frequency as shown in the following Table 18-1. The f_S is selected to f_{SUB} (sub clock) which is 32.768kHz.

LCR[1:0]	LCD clock	Frame Frequency (Hz)	
		Duty = 1/4	Duty = 1/8
00	$f_{SUB} \div 32$	128	64
01	$f_{SUB} \div 64$	64	32
10	$f_{SUB} \div 128$	32	16
11	$f_{SUB} \div 256$	16	8

Table 18-1 Setting of LCD Frame Frequency

The matters to be attended to use LCD driver

In reset state, LCD source clock is sub clock. So, when the power is supplied, the LCD display would be flickered be-

fore the oscillation of sub clock is stabilized. It is recommended to use LCD display on after the stabilization time of sub clock is considered enough.

18.2 LCD BIAS Control

The MC80F7708 has internal Bias Circuit for driving LCD panel. It also has the contrast controller of 16 step.

The LCD Bias control register and internal Bias circuit is as shown in the Figure 18-3.

The SYS_BIR[1:0] and BIF of LBCR register is used for controlling BIR. Refer to “24. Built In Reset (BIR)”

Note: The self bias check reference can be applied to contrast adjustment with VDD voltage variation. Because the VDD voltage can be calculated by reading the ADC value of self bias check reference. Writing appropriate value to CTR[3:0] with VDD level, LCD contrast variation with VDD can be reduced.

Figure 18-3 LCD Bias Control

18.3 LCD Display Memory

Display data are stored to the display data area (page 4) in the data memory.

The display data which stored to the display data area (address 0460_H-0473_H) are read automatically and sent to the LCD driver by the hardware. The LCD driver generates the segment signals and common signals in accordance with the display data and drive method. Therefore, display patterns can be changed by only overwriting the contents of the display data area with a program. The table look up instruction is mainly used for this overwriting.

Figure 18-4 shows the correspondence between the display data area and the SEG/COM pins. The LCD lights when the display data is “1” and turn off when “0”.

The SEG data for display is controlled by RPR (RAM Paging Register).

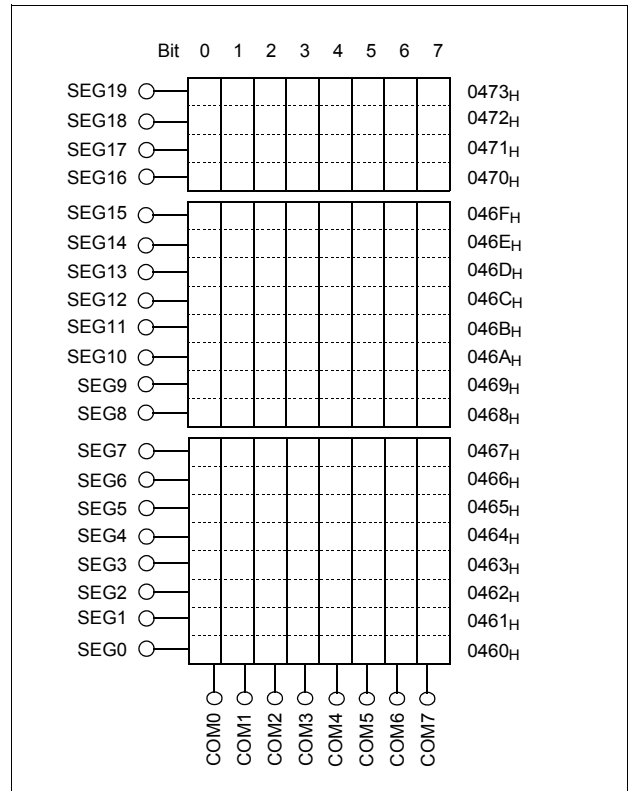

Figure 18-4 LCD Display Memory

18.4 Control Method of LCD Driver

Initial Setting

Flow chart of initial setting is shown in Figure 18-5.

Example: Driving of LCD

Figure 18-5 Initial Setting of LCD Driver

Figure 18-6 Example of Connection COM & SEG

Display Data

Normally, display data are kept permanently in the program memory and then stored at the display data area by the table look-up instruction. This can be explained using character display with 1/4 duty LCD as an example as well as any LCD panel. The COM and SEG connections to the LCD and display data are the same as those shown in Figure 18-6. Following is showing the programming example for displaying character.

Note: When power on RESET, sub oscillation start up time is required. Enable LCD display after sub oscillation is stabilized, or LCD may occur flicker at power on time shortly.

18.5 Duty and Bias Selection of LCD Driver

4 kinds of driving methods can be selected by LCDD[1:0] (bits 3 and 2 of LCD control register) and connection of BIAS pin exter-

nally. Figure 18-8 shows typical driving waveforms for LCD.)

Figure 18-8 LCD Drive Waveform (Voltage COM-SEG Pins)

19. UNIVERSAL ASYNCHRONOUS SERIAL INTERFACE

The Asynchronous serial interface(UART) enables full-duplex operation wherein one byte of data after the start bit is transmitted and received. The on-chip baud rate generator dedicated to UART enables communications using a wide range of selectable baud rates.

The UART driver consists of TXSR0, RXBR0, ASIMR0 and BRGCR0 register. Clock asynchronous serial I/O mode (UART) can be selected by ASIMR register. Figure 19-1 shows a block diagram of the serial interface (UART).

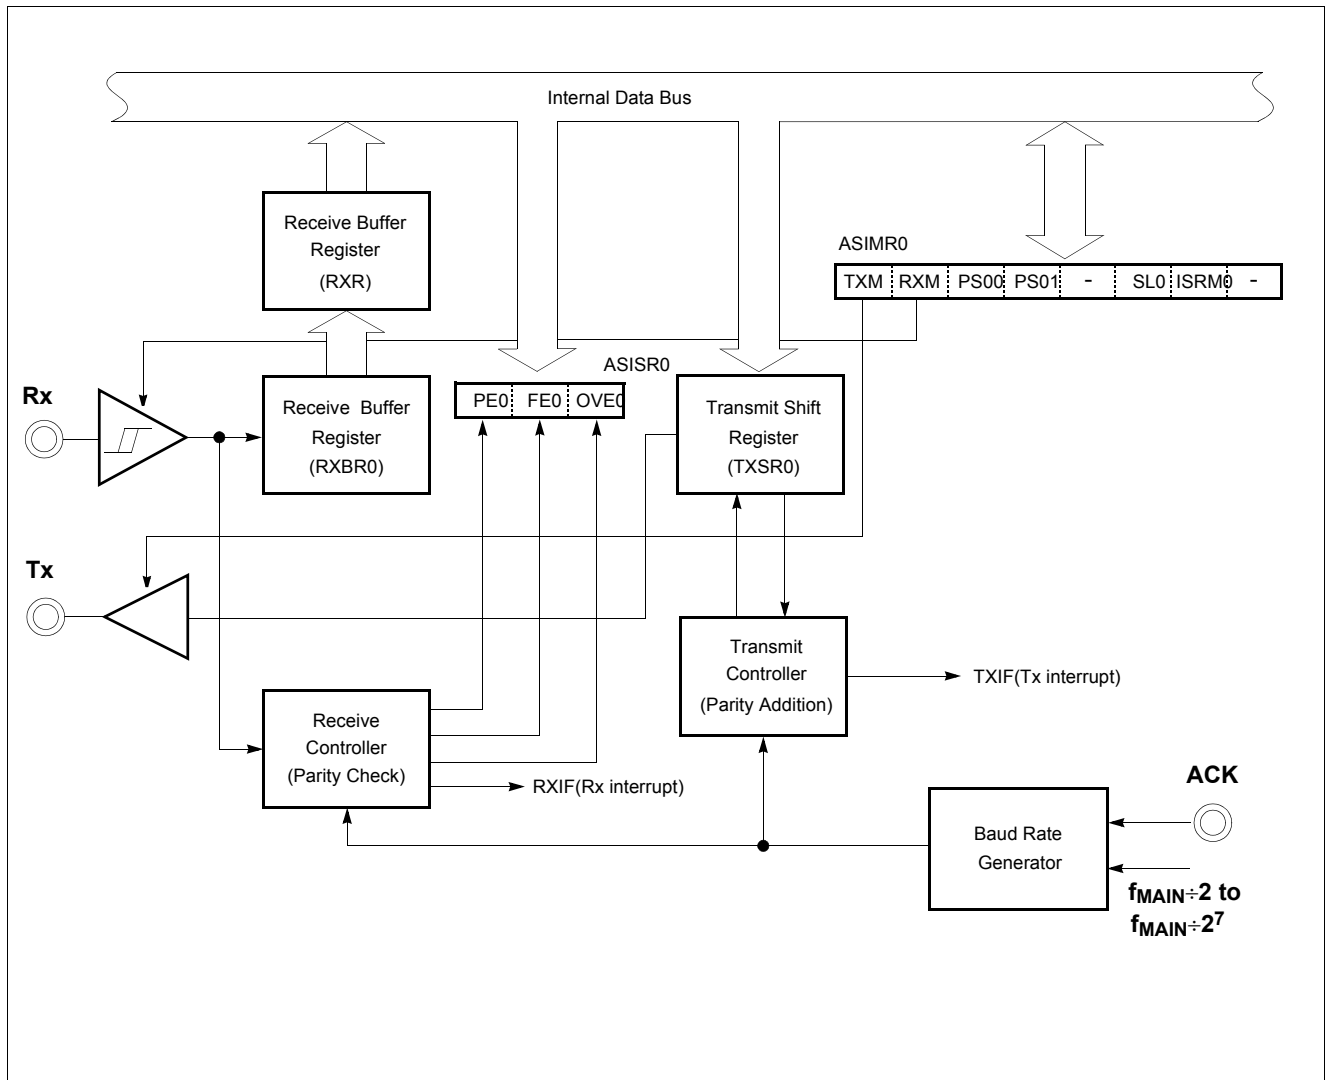

Figure 19-1 UART Block Diagram

Figure 19-2 Baud Rate Generator Block Diagram

19.1 Asynchronous Serial Interface Configuration

The asynchronous serial interface (UART) consists of the following hardware.

Item	Configuration
Register	Transmit shift register (TXSR0) Receive buffer register (RXBR0)
Control register	Asynchronous serial interface mode register (ASIMR0) Baudrate generator control register (BRGCR0)

Table 19-1 Serial Interface Configuration

Transmit Shift Register (TXSR0)

This is the register for setting transmit data. Data written to TXSR0 is transmitted as serial data. When the data length is set as 7 bit, bit 0 to 6 of the data written to TXSR0 are transferred as transmit data. Writing data to TXSR0 starts the transmit operation. TXSR0 can be written by an 8 bit memory manipulation instruction. It cannot be read.

Note: Do not write to TXSR0 during a transmit operation. The same address is assigned to TXSR0 and the receive buffer register (RXBR0). A read operation reads values

from RXBR0.

Receive Buffer Register (RXBR0)

This register is used to hold received data. When one byte of data is received, one byte of new received data is transferred from the receive shift register. When the data length is set as 7 bits, received data is sent to bits 0 to 6 of RXBR0. In this case, the MSB of RXBR0 always becomes 0. RXBR0 can be read by an 8 bit memory manipulation instruction. It cannot be written.

Note: The same address is assigned to RXBR0 and the transmit shift register (TXSR0). During a write operation, values are written to TXSR0.

Asynchronous serial interface mode control register (ASIMR0)

This is an 8 bit register that controls asynchronous serial interface (UART)'s serial transfer operation. ASIMR0 is set by a 1 bit or 8 bit memory manipulation instruction.

Baud rate generator control register (BRGCR0)

This register sets the serial clock for asynchronous serial interface. BRGCR0 is set by an 8 bit memory manipulation instruction.

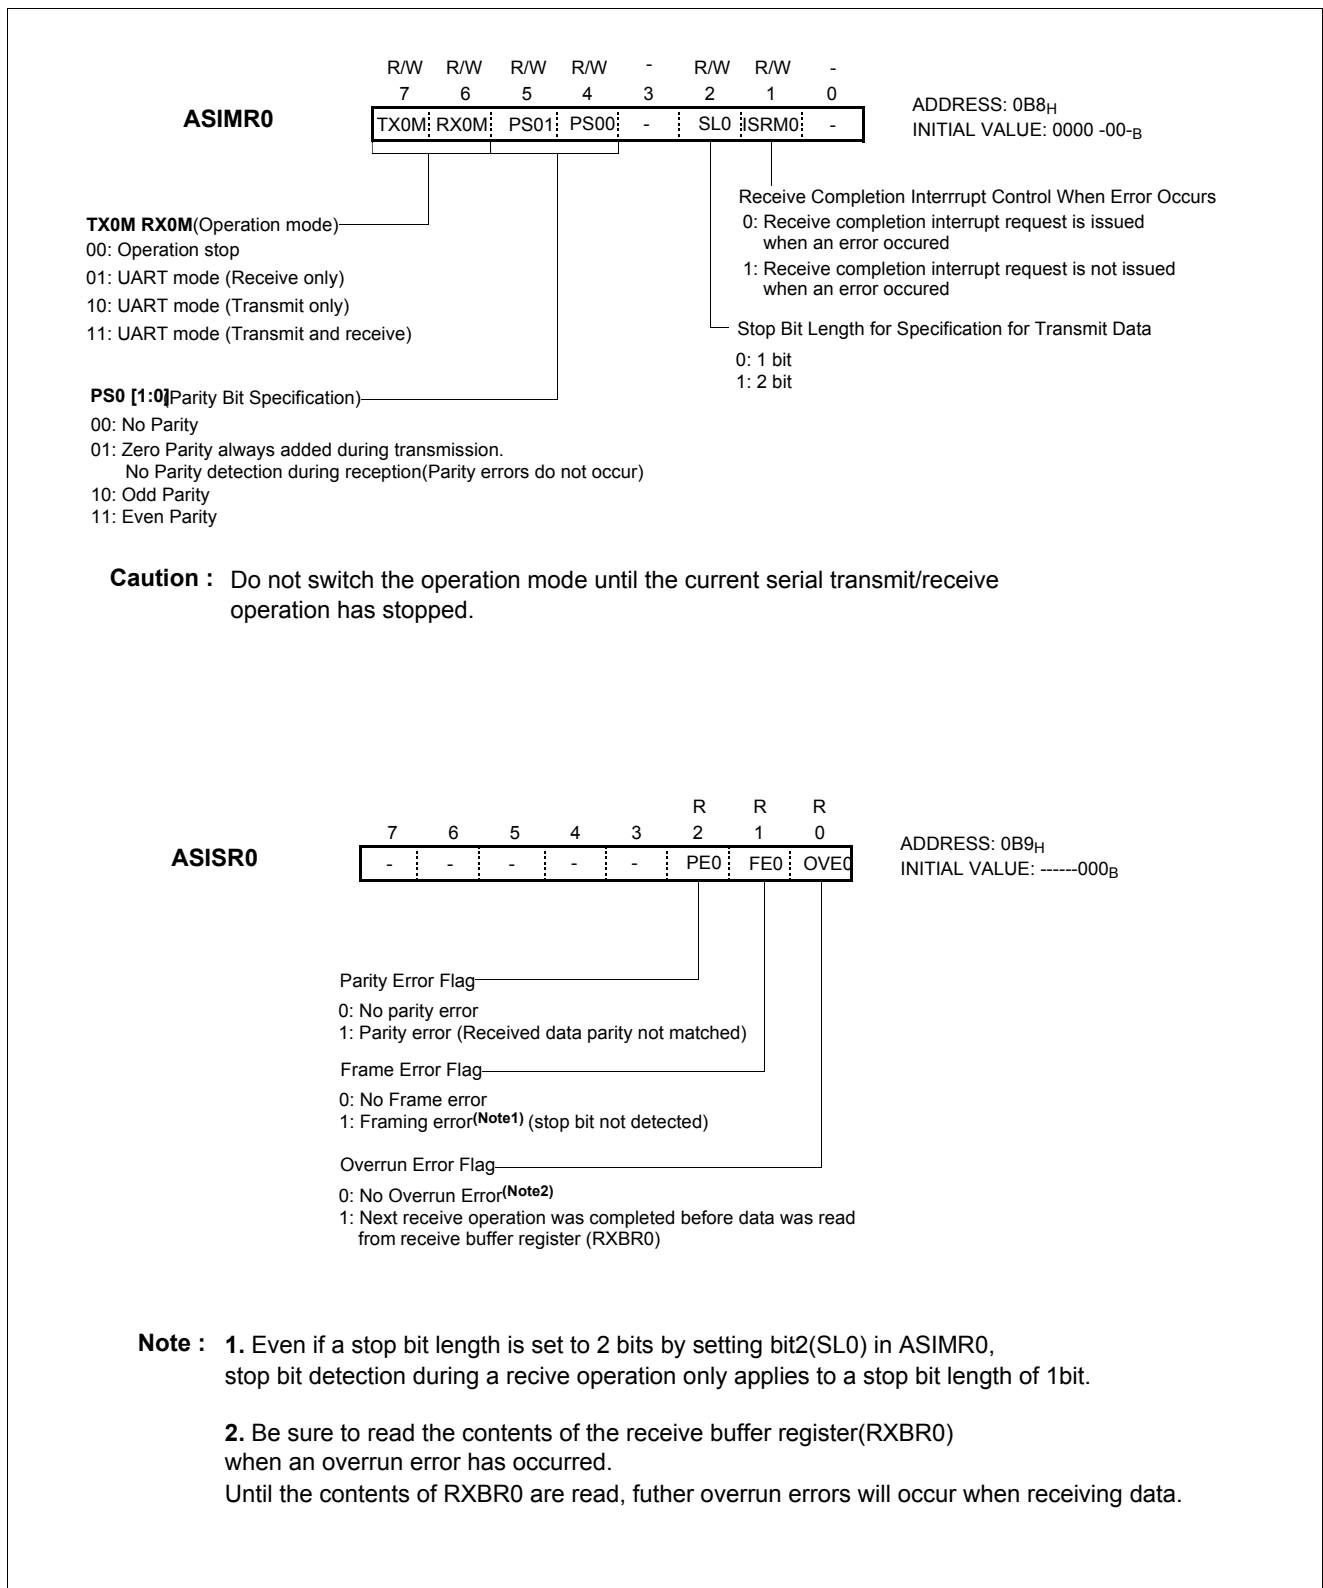

Figure 19-1 Asynchronous Serial Interface Mode & Status Register

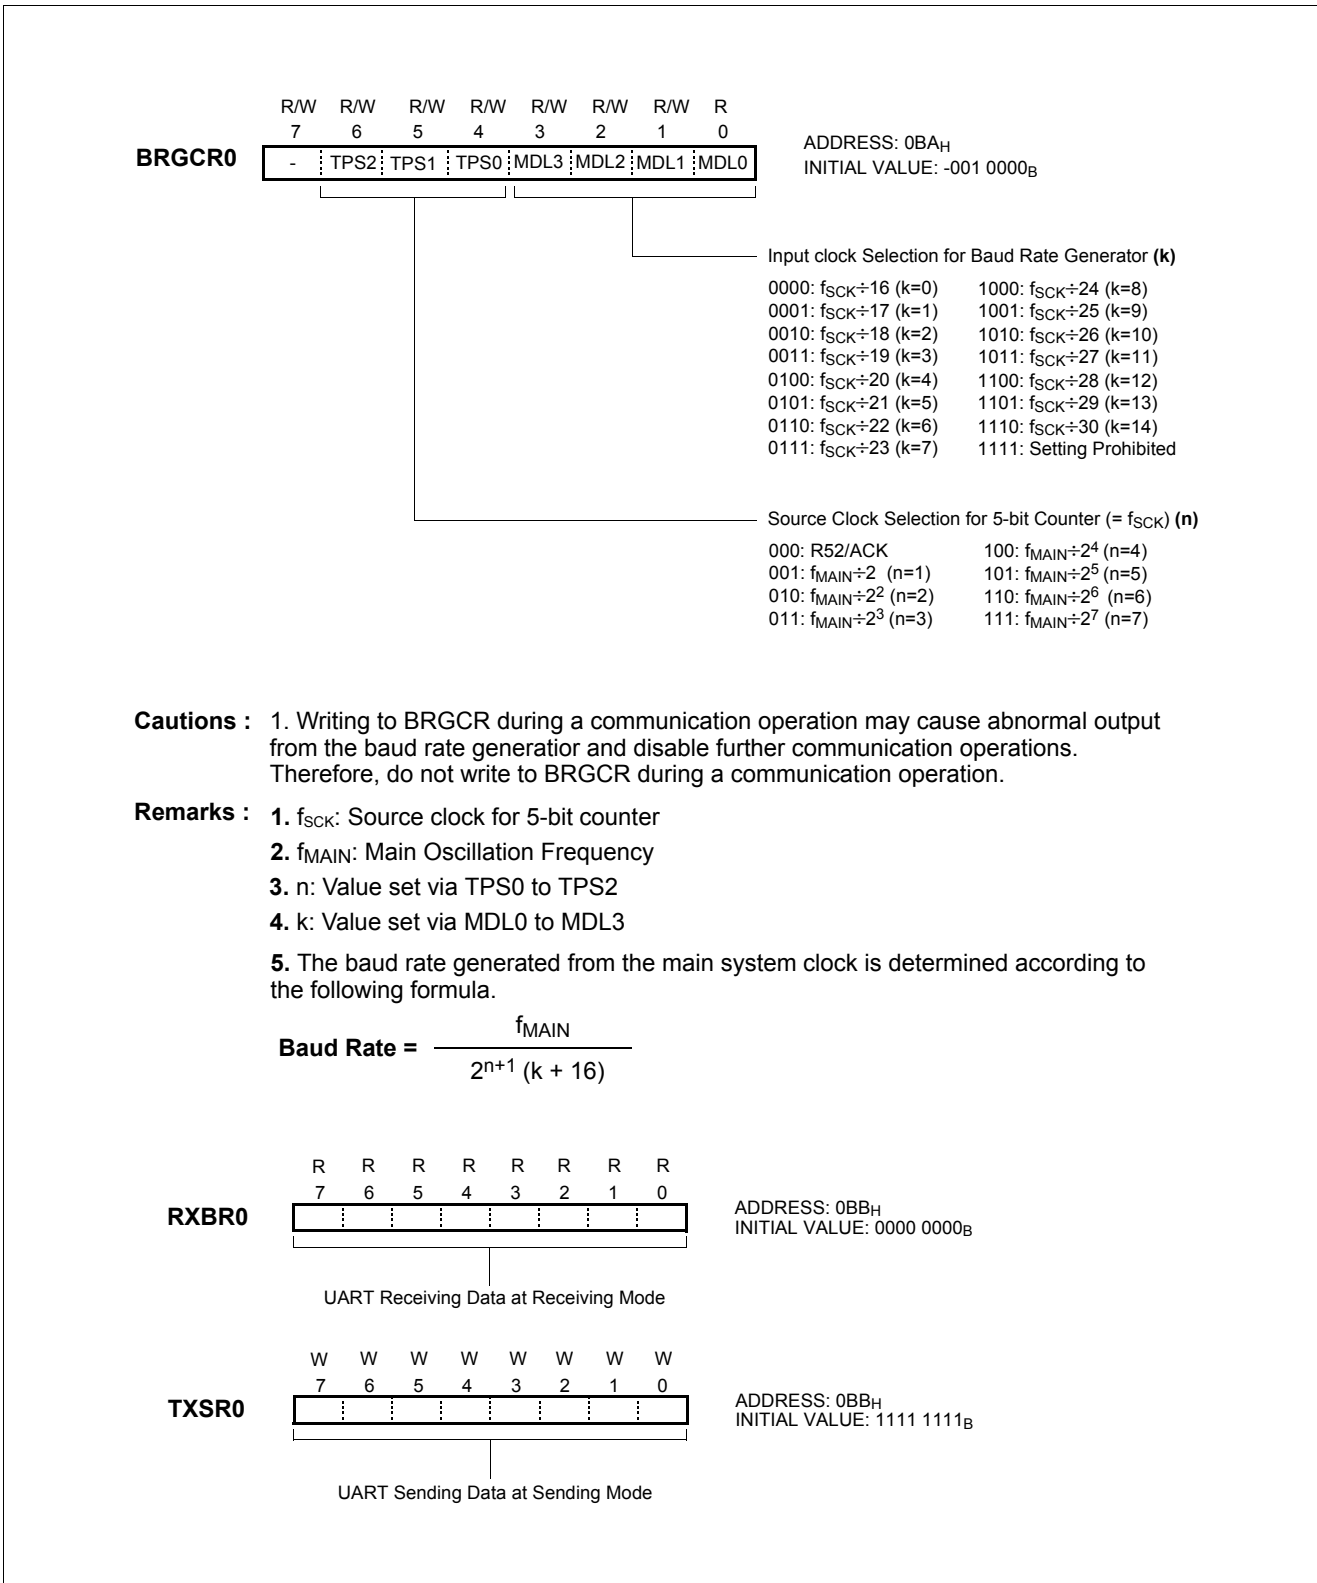

Figure 19-2 Baud Rate Generator Control Register, Receive Buffer Register, Transmit shift Register

19.2 Relationship between main clock and baud rate

The transmit/receive clock that is used to generate the baud rate is obtained by dividing the main system clock. Transmit/Receive clock generation for baud rate is made by using main system clock which is divided.

The baud rate generated from the main system clock is determined according to the following formula

$$BaudRate = \frac{fx}{2^{n+1}(K+16)}$$

- fx : main system clock oscillation frequency
- n : value set via TPS0 to TPS1 (1 ≤ n ≤ 7)
- k : value set via MDL0 to MDL3 (0 ≤ n ≤ 14)

Baud Rate (bps)	fx = 11.0592M		fx = 8.00M		fx = 7.3728M		fx = 6.00M		fx = 5.00M		fx = 4.1943	
	BRGCR	Err (%)	BRGCR	Err (%)	BRGCR	Err (%)	BRGCR	Err (%)	BRGCR	Err (%)	BRGCR	Err (%)
600	-	-	-	-	-	-	-	-	-	-	7BH	1.14
1,200	-	-	7AH	0.16	78H	0.00	73H	2.79	70H	1.73	6BH	1.14

Table 19-2 Relationship Between Main Clock and Baud Rate

20. OPERATION MODE

The system clock controller starts or stops the main frequency clock oscillator, which is controlled by system clock mode register (SCMR). Figure 20-1 shows the operating mode transition diagram.

System clock control is performed by the system clock mode register (SCMR). During reset, this register is initialized to “0” so that the main-clock operating mode is selected.

Main Active mode

This mode is fast-frequency operating mode. The CPU and

the peripheral hardwares are operated on the high-frequency clock. At reset release, this mode is invoked.

SLEEP mode

In this mode, the CPU clock stops while peripherals and the oscillation source continue to operate normally.

STOP mode

In this mode, the system operations are all stopped, holding the internal states valid immediately before the stop at the low power consumption level.

Figure 20-1 Operating Mode

20.1 Operation Mode Switching

Shifting from the Normal operation to the SLEEP mode

By writing “0FH” into SSCR which will be explained in "21.1 SLEEP Mode" on page 90, the CPU clock stops and the SLEEP mode is invoked. The CPU stops while other peripherals are operate normally.

The way of release from this mode is RESET and all available interrupts.

For more detail, See "21.1 SLEEP Mode" on page 90

Shifting from the Normal operation to the STOP mode

By writing “5AH” into SSCR and then executing STOP instruction, the main-frequency clock oscillation stops and the STOP mode is invoked. But sub-frequency clock oscillation is operated continuously.

After the STOP operation is released by reset, the operation mode is changed to Main active mode.

The methods of release are RESET, Key scan interrupt, Watch Timer interrupt, Timer/Event counter1 (EC0 pin) and External Interrupt.

For more details, see "21.2 STOP Mode" on page 91.

Note: In the STOP and SLEEP operating modes, the power consumption by the oscillator and the internal hardware is reduced. However, the power for the pin interface (depending on external circuitry and program) is not directly associated with the low-power consumption operation. This must be considered in system design as well as interface circuit design.

21. POWER DOWN OPERATION

MC80F7708 have 2 power down mode. In power down mode, power consumption is reduced considerably in Battery operation that Battery life can be extended a lot.

Sleep mode is entered by writing “0FH” into Stop and Sleep Control Register(SSCR), and STOP mode is entered by writing “5AH” into SSCR and then executing STOP instruction.

21.1 SLEEP Mode

In this mode, the internal oscillation circuits remain active.

Oscillation continues and peripherals are operate normally but CPU stops. The status of all Peripherals in this mode is shown in Table 21-1. Sleep mode is entered by writing “0FH” into SSCR (address 0E9H).

It is released by RESET or all interrupt. To be released by interrupt, interrupt should be enabled before Sleep mode.

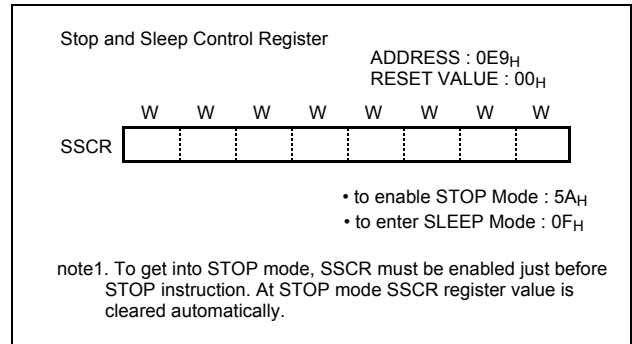

Figure 21-1 SLEEP Mode Register

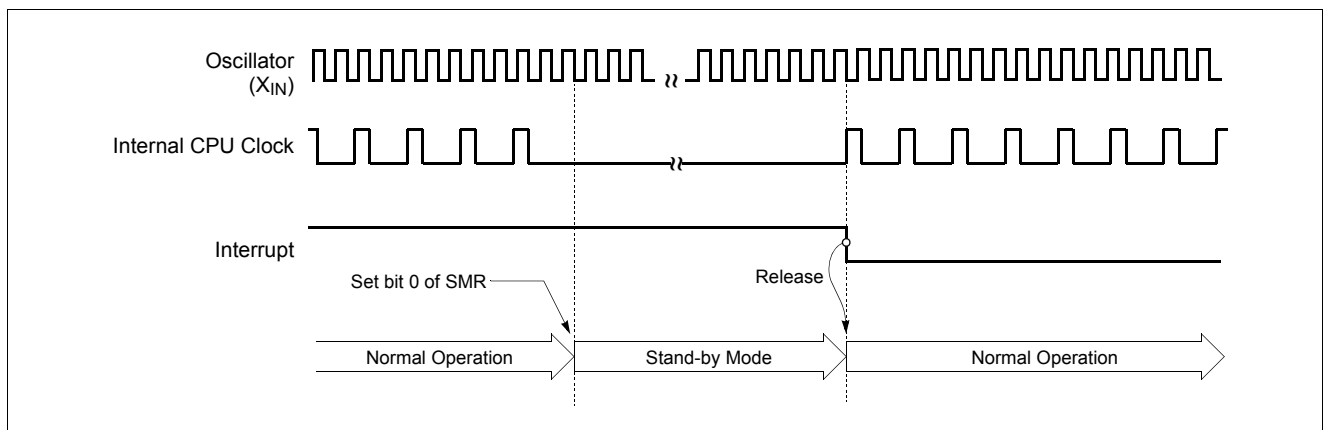

Figure 21-2 Sleep Mode Release Timing by External Interrupt

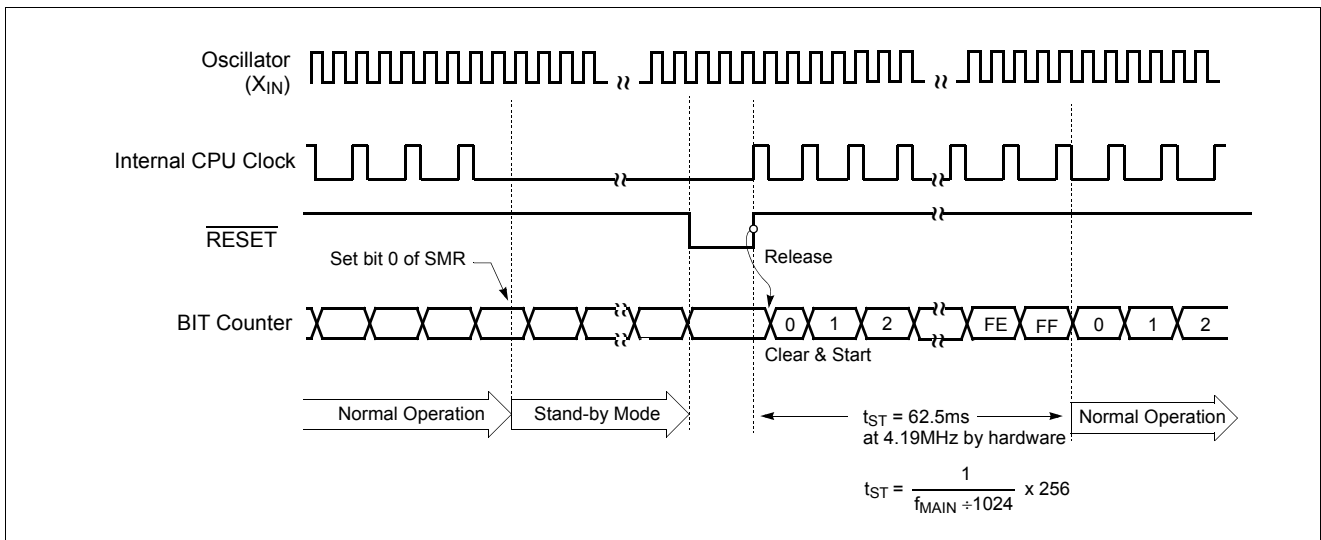

Figure 21-3 SLEEP Mode Release Timing by RESET pin

21.2 STOP Mode

For applications where power consumption is a critical factor, this device provides STOP mode for reducing power consumption.

Start The Stop Operation

The STOP mode can be entered by STOP instruction during program execution. In Stop mode, the on-chip main-

frequency oscillator, system clock, and peripheral clock are stopped (Watch timer clock is oscillating continuously). With the clock frozen, all functions are stopped, but the on-chip RAM and Control registers are held. The port pins output the values held by their respective port data register and the port direction registers. The status of peripherals during Stop mode is shown below.

Peripheral	STOP Mode	Sleep Mode
CPU	All CPU operations are disabled	All CPU operations are disabled
RAM	Retain	Retain
LCD driver	Operates continuously	Operates continuously
Basic Interval Timer	Halted	Operates continuously
Timer/Event counter 0	Halted (Only when the Event counter mode is enabled, Timer 0 operates normally)	Timer/Event counter 0 operates continuously
Watch Timer	Operates continuously	Operates continuously
Main-oscillation	Stop (X _{IN} =L, X _{OUT} =L)	Oscillation ¹
Sub-oscillation	Oscillation	Oscillation
I/O ports	Retain	Retain
Control Registers	Retain	Retain
Release method	by RESET, Watch Timer interrupt, Timer interrupt (EC0), and External interrupt	by RESET, All interrupts

Table 21-1 Peripheral Operation during Power Down Mode

1. Refer to the Table 10-2

Operating Clock source	Main Operating Mode	Main Sleep Mode	Stop Mode
Main Clock	Oscillation	Oscillation	Stop
Sub Clock	Oscillation	Oscillation	Oscillation
System Clock	Active	Stop	Stop
Peri. Clock	Active	Active	Stop ¹

1. Except watch timer(sub clock) and LCD driver(sub clock)

Table 21-2 Clock Operation of STOP and SLEEP mode

Note: Since the X_{IN} pin is connected internally to GND to avoid current leakage due to the crystal oscillator in STOP mode, do not use STOP instruction when an external clock is used as the main system clock.

In the Stop mode of operation, V_{DD} can be reduced to minimize power consumption. Be careful, however, that V_{DD} is not reduced before the Stop mode is invoked, and that V_{DD} is restored to its normal operating level before the Stop mode is terminated.

The reset should not be activated before V_{DD} is restored to its normal operating level, and must be held active long enough to allow the oscillator to restart and stabilize. And after STOP instruction, at least two or more NOP instruction should be written as shown in example below.

Example)

```

:
LDM CKCTLR, #0000_1111B
STOP
NOP
NOP
:

```

The Interval Timer Register CKCTLR should be initialized by software in order that oscillation stabilization time should be longer than 20ms before STOP mode.

Release the STOP mode

The exit from STOP mode is using hardware reset or external interrupt, watch timer or timer interrupt (EC0).

To release STOP mode, corresponding interrupt should be enabled before STOP mode.

Specially as a clock source of Timer/Event counter, EC0 pin can release it by Timer/Event counter Interrupt request.

Reset redefines all the control registers but does not change the on-chip RAM. External interrupts allow both on-chip RAM and Control registers to retain their values.

Start-up is performed to acquire the time for stabilizing oscillation. During the start-up, the internal operations are all stopped.

Figure 21-4 STOP Mode Release Timing by External Interrupt

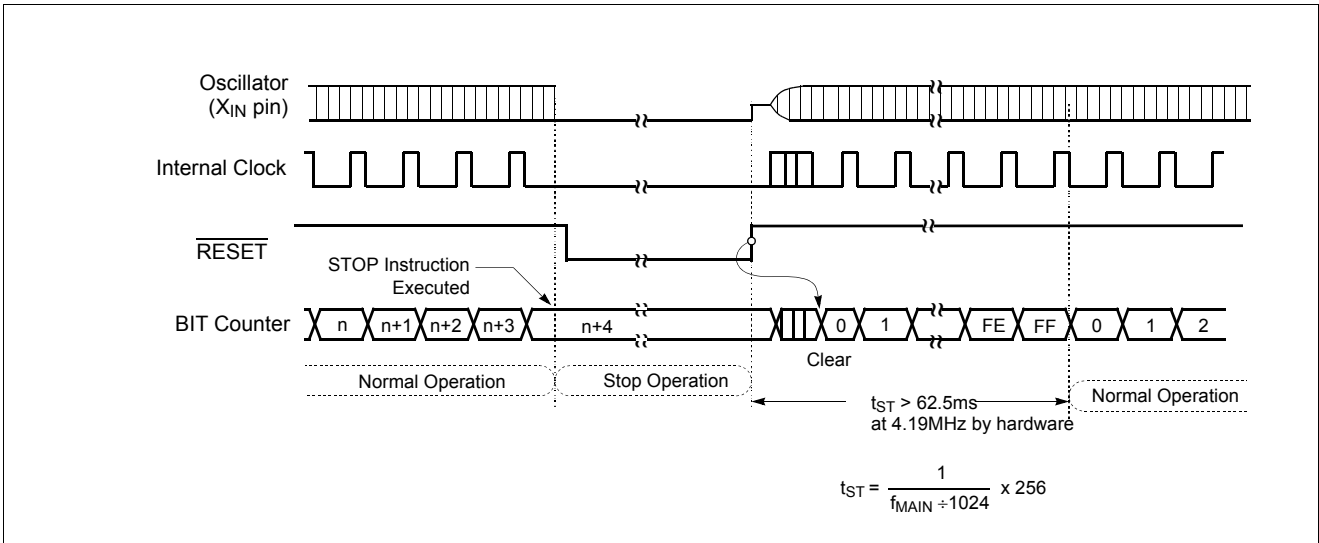

Figure 21-5 STOP Mode Release Timing by RESET

Minimizing Current Consumption

The Stop mode is designed to reduce power consumption. To minimize current drawn during Stop mode, the user should turn-off output drivers that are sourcing or sinking current, if it is practical.

Note: In the STOP operation, the power dissipation associated with the oscillator and the internal hardware is lowered; however, the power dissipation associated with the pin interface (depending on the external circuitry and program) is not directly determined by the hardware operation of the STOP feature. This point should be little current flows when the input level is stable at the power voltage level (V_{DD}/V_{SS}); however, when the input level becomes higher than the power voltage level (by approximately 0.3V), a current begins to flow. Therefore, if cutting off the output transistor at an I/O port puts the pin signal into the high-impedance state, a current flow across the ports input transistor, requiring it to fix the level by pull-up or other means.

It should be set properly that current flow through port doesn't exist.

First consider the setting to input mode. Be sure that there is no current flow after considering its relationship with external circuit. In input mode, the pin impedance viewing from external MCU is very high that the current doesn't flow.

But input voltage level should be V_{SS} or V_{DD} . Be careful that if unspecified voltage, i.e. if uniformed voltage level (not V_{SS} or V_{DD}) is applied to input pin, there can be little current (max. 1mA at around 2V) flow.

If it is not appropriate to set as an input mode, then set to output mode considering there is no current flow. Setting to High or Low is decided considering its relationship with external circuit. For example, if there is external pull-up resistor then it is set to output mode, i.e. to High, and if there is external pull-down resistor, it is set to low.

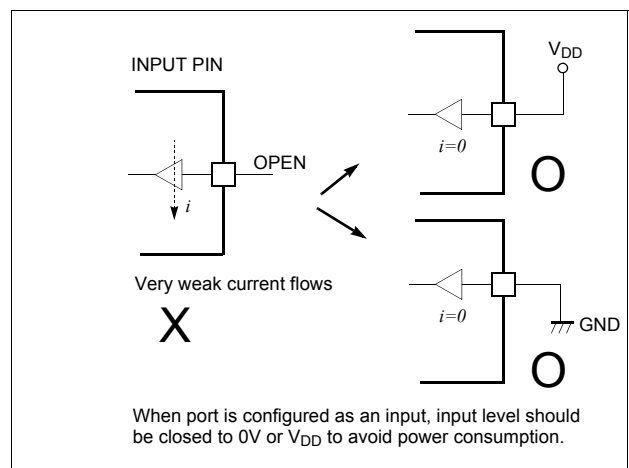

Figure 21-6 Application Example of Unused Input Port

When port is configured as an input, input level should be closed to 0V or V_{DD} to avoid power consumption.

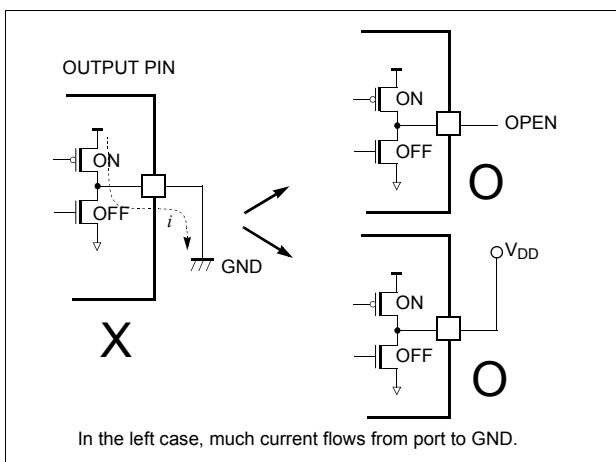

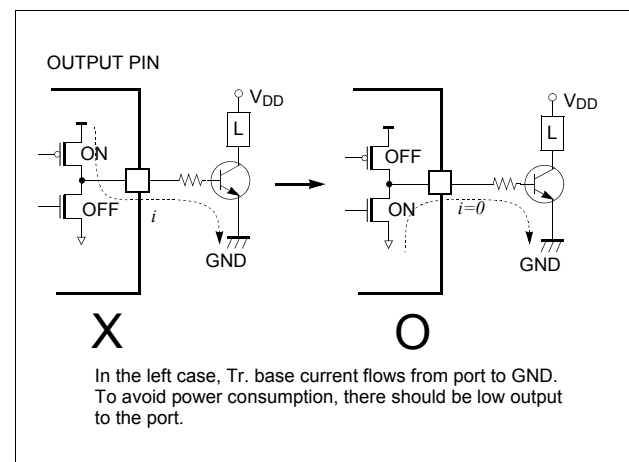

Figure 21-7 Application Example of Unused Output Port

In the left case, Tr. base current flows from port to GND. To avoid power consumption, there should be low output to the port.

22. OSCILLATOR CIRCUIT

The MC80F7708 have three oscillation circuits internally. X_{IN} and X_{OUT} are input and output for main frequency and SX_{IN} and SX_{OUT} are input and output for sub frequency,

respectively, inverting amplifier which can be configured for being used as an on-chip oscillator, as shown in Figure 22-1.

Figure 22-1 Oscillation Circuit

Oscillation circuit is designed to be used either with a ceramic resonator or crystal oscillator. Since each crystal and ceramic resonator have their own characteristics, the user should consult the crystal manufacturer for appropriate values of external components.

In addition, see Figure 22-2 for the layout of the crystal.

Note: Minimize the wiring length. Do not allow the wiring to intersect with other signal conductors. Do not allow the wiring to come near changing high current. Set the potential of the grounding position of the oscillator capacitor to that of V_{SS} . Do not ground it to any ground pattern where high current is present. Do not fetch signals from the oscillator.

Figure 22-2 Layout of Oscillator PCB circuit

23. RESET

The MC80F7708 have has four reset generation sources; external reset input, power on reset (POR), built in reset

(BIR) and watch-dog timer reset. Table 23-1 shows on-chip hardware initialization by reset action.

On-chip Hardware	Initial Value
Program counter (PC)	(FFFF _H) - (FFFE _H)
RAM page register (RPR)	0
G-flag (G)	0

On-chip Hardware	Initial Value
Operation mode	Main-frequency clock
Peripheral clock	On
Control registers	Refer to Table 8-1 on page 28

Table 23-1 Initializing Internal Status by Reset Action

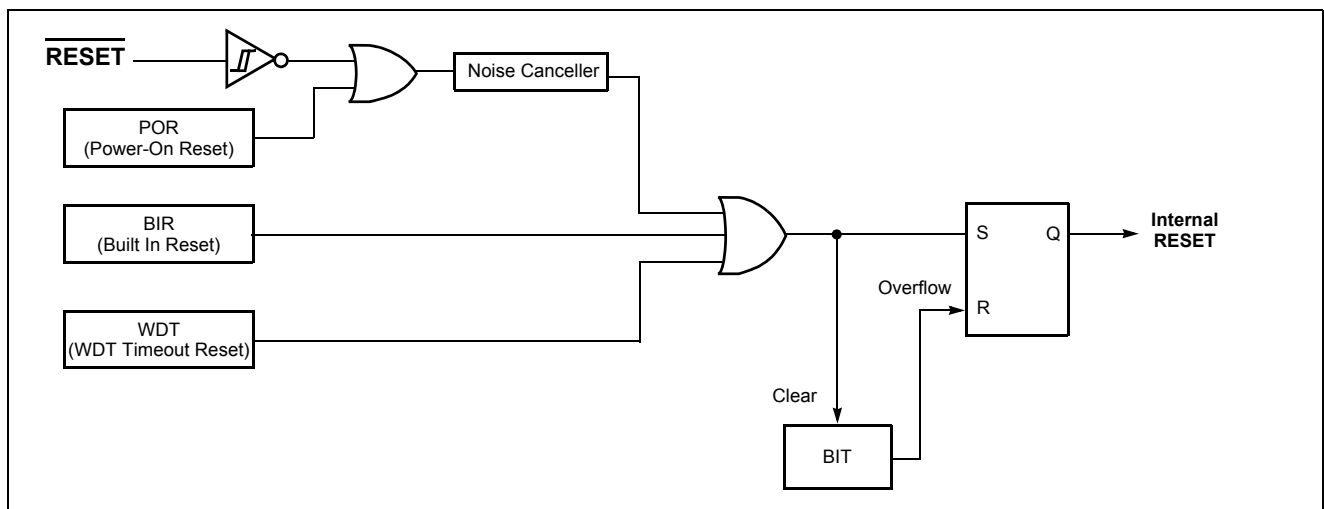

Figure 23-1 RESET Block Diagram

23.1 External Reset Input

The reset input is the $\overline{\text{RESET}}$ pin, which is the input to a Schmitt Trigger. A reset accomplished by holding the $\overline{\text{RESET}}$ pin to low for at least 8 oscillator periods, within the operating voltage range and oscillation stable, it is applied, and the internal state is initialized. After reset, 65.5ms (at 4MHz) and 7 oscillator periods are required to start execution as shown in Figure 23-3.

Internal User RAM is not affected by reset. When V_{DD} is turned on, the RAM content is indeterminate. Therefore, this RAM should be initialized before read or tested it.

When the $\overline{\text{RESET}}$ pin input goes to high, the reset operation is released and the program execution starts at the vector address stored at FFFE_H - FFFF_H.

A connection for normal power-on-reset is shown in Figure 23-2.

Figure 23-2 Normal Power-on-Reset Circuit

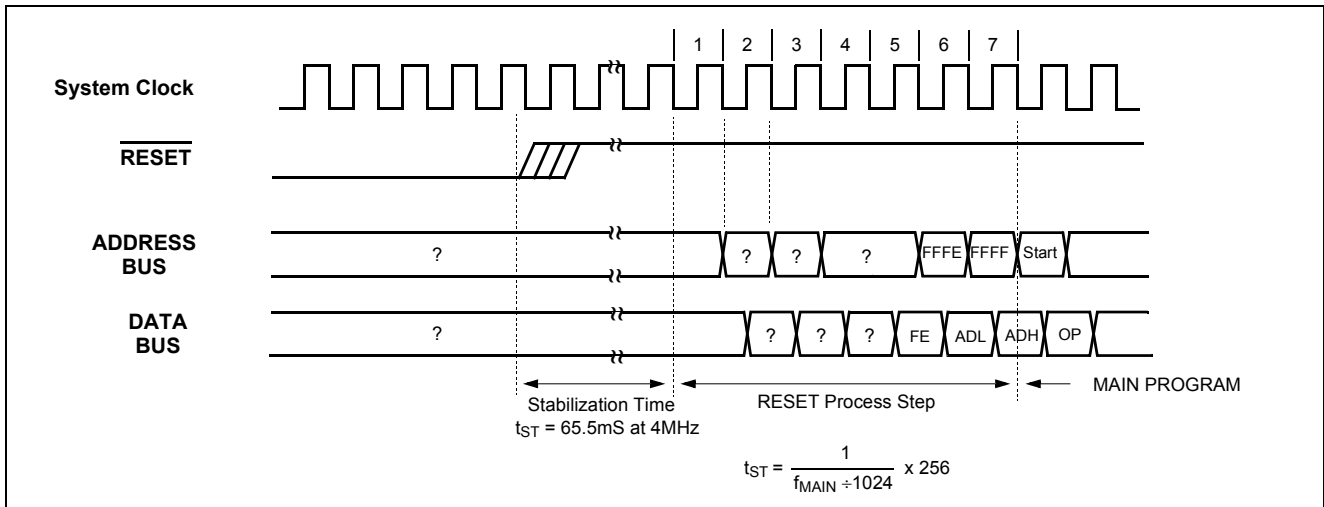

Figure 23-3 Timing Diagram of RESET

23.2 Power On Reset

The on-chip POR circuit holds down the device in RESET until V_{DD} has reached a high enough level for proper operation. It will eliminate external components such as reset IC or external resistor and capacitor for external reset circuit. In addition that the \overline{RESET} pin can be used to normal input port R47 by setting “POR” and “R47EN” bit of the Configuration option area(20FFH) in Flash programming. When the device starts normal operation, its operating

parameters (voltage, frequency, temperature...etc) must be met.

Note: When “POR” option is checked and “R47EN” option is not checked, $\overline{RESET}/R47$ pin acts as external Reset input pin. In this case, the external reset circuit should be connected to \overline{RESET} pin. If external reset is not needed, not only “POR”, but also “R47EN” option should be checked.

23.3 Built In Reset

Refer to “24. Built In Reset (BIR)”

23.4 Watchdog Timer Reset

Refer to “14. WATCH DOG TIMER”

The BIR of MC80F7708 has 8 detection level which can be selected by BIS[2:0] and each level can be trimmed by TRM[1:0].

The NC_SEL bit of BIRR is used for selecting BIR noise canceller. For example, if the NC_SEL bit of BIRR is set to “1” and VDD voltage falls below the BIR detection level during 20us, BIR does not generate internal reset signal or freeze mode signal because the 32us noise canceller eliminates low level detection signal less than 32us.

BIR result can be selected by SYS_BIR[1:0] of LBCR register. When SYS_BIR[1:0] is set to “00”, BIR generates reset signal. If SYS_BIR[1:0] is set to “10”, it generates freeze mode signal and CPU freeze until the VDD voltage returns to regular level.

The self bias check reference, which can be used for calculating VDD voltage, can be activated by setting the AD_REFB bit to “0” and BIR_ENB bit to “0”. It is used for checking VDD voltage.

BIF is set to “1” when BIR occurs. It can be used to distinguish reset caused by BIR and other.

When the POR is used, the BIR detection level should be set to the level less than POR level. If the POR level is

2.4V, BIR level 2V and 2.4V can not operate.

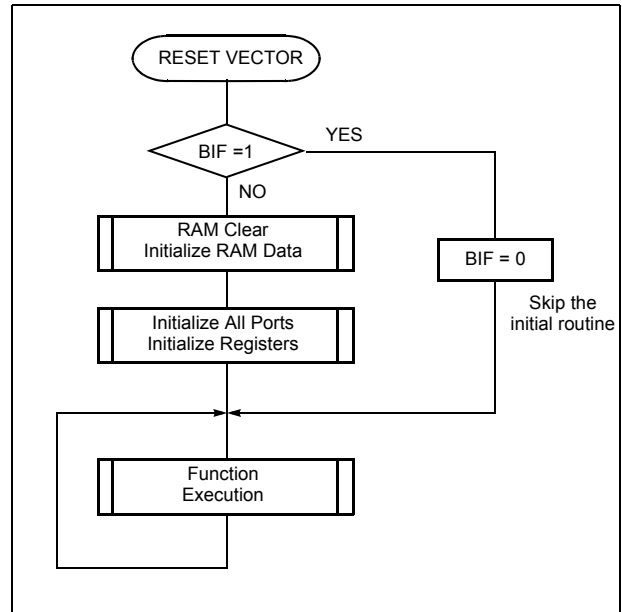

Figure 24-2 Example Flow of Reset flow by BIR

25. Oscillation Noise Protector

The Oscillation Noise Protector (ONP) is used to supply stable internal system clock by excluding the noise which could be entered into oscillator and recover the oscillation fail. This function could be enabled or disabled by the “ONP” bit of the Device configuration area (20FFH) for the MC80F7708.

The ONP function is like below.

- Recovery the oscillation wave crushed or loss caused

by high frequency noise.

- Change system clock to the internal oscillation clock when the high frequency noise is continuing.
- Change system clock to the internal oscillation clock when the X_{IN}/X_{OUT} is shorted or opened, the main oscillation is stopped except by stop instruction and the low frequency noise is entered.

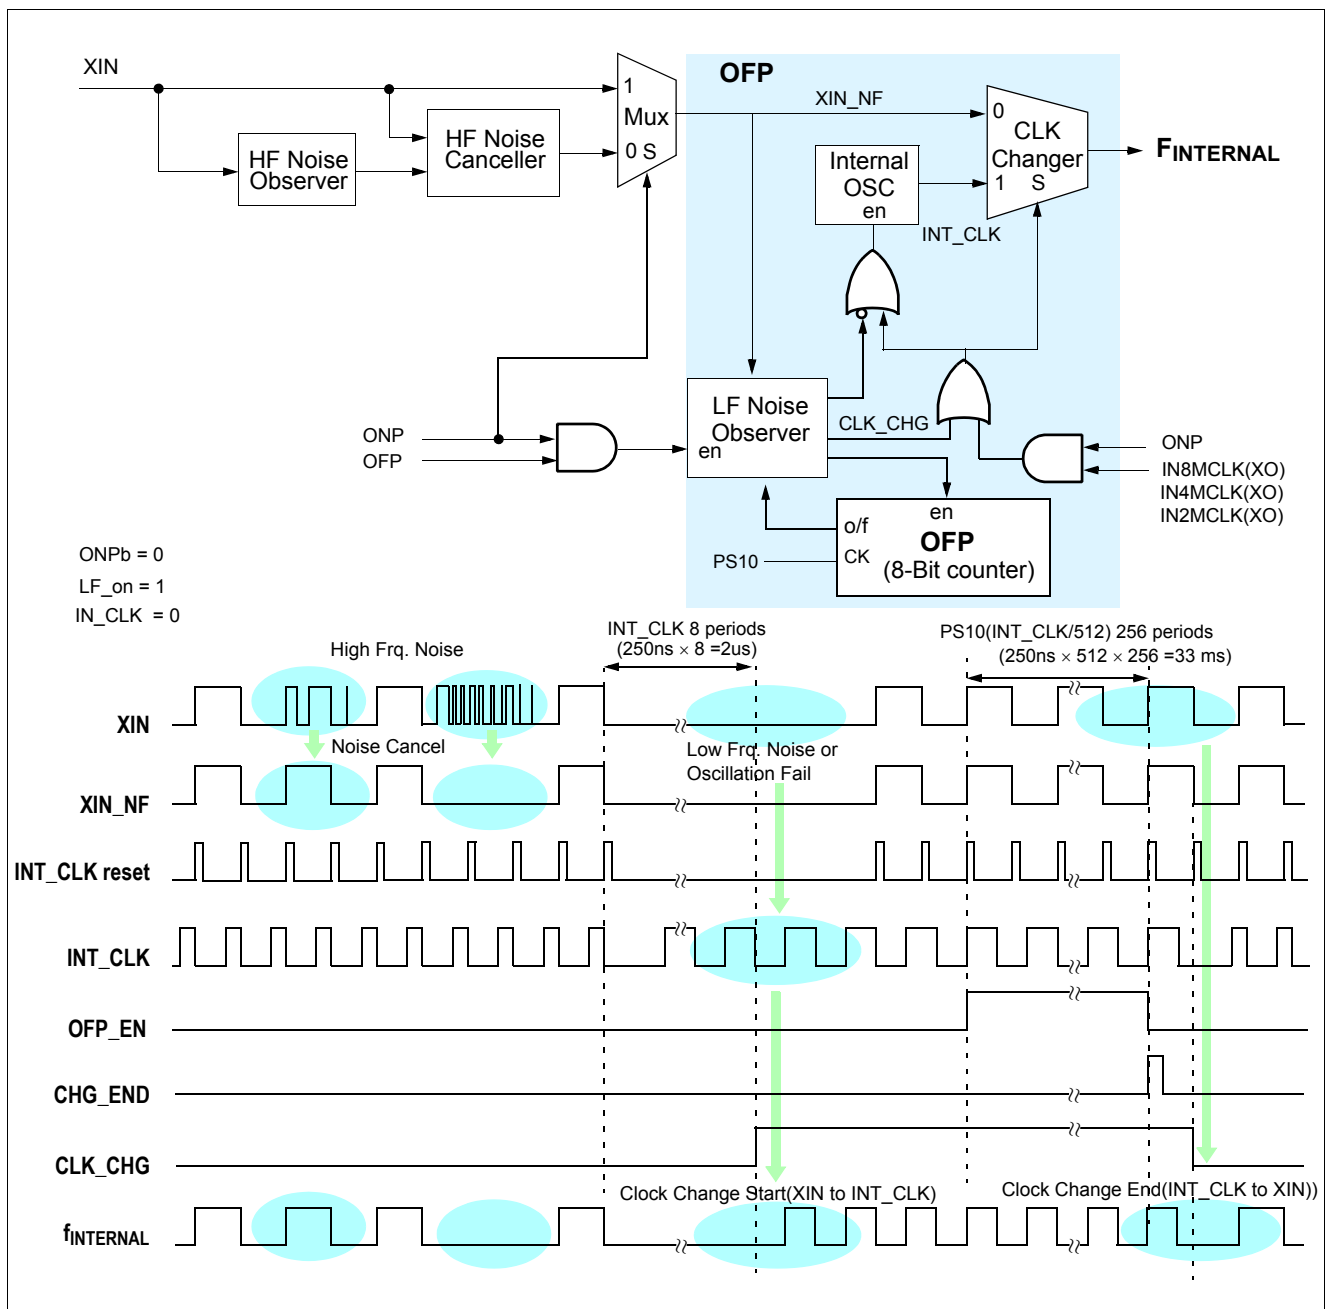

Figure 25-1 Block Diagram of ONP & OFF and Respective Wave Forms

The oscillation fail processor (OFP) can change the clock source from external to internal oscillator when the oscillation fail occurred. This function could be enabled or disabled by the “OFP” bit of the Device Configuration Area (MASK option for MC80F7708).

And this function can recover the external clock source when the external clock is recovered to normal state.

The “IN8MCLK”, “IN4MCLK”, “IN2MCLK”,

“IN8MCLKXO”, “IN4MCLKXO”, “IN2MCLKXO” option of the Device Configuration Area enables the function to operate the device by using the internal oscillator clock in ONP block as system clock. There is no need to connect the x-tal, resonator, RC and R externally. After selecting the this option, the period of internal oscillator clock could be checked by X_{OUT} outputting clock divided the internal oscillator clock by 4.

26. FLASH PROGRAMMING SPEC.

26.1 FLASH Configuration Byte

Except the user program memory, there is configuration byte(address 20FF_H) for the selection of program lock, ONP, OPF, oscillation configuration and reset configuration. The configuration byte of FLASH is shown as Figure 26-1. It could be served when user use the FLASH programmer.

Note: The Configuration Option may not be read exactly when VDD rising time is very slow. It is recommended to adjust the VDD rising time faster than 40ms/V (200ms from 0V to 5V).

Figure 26-1 The FLASH Configuration Byte

26.2 FLASH Programming

The MC80F7708 is a MTP microcontroller. Its internal user memory is constructed with FLASH ROM.

Blank FLASH's internal memory is filled by 00_H, not FF_H.

Note: In any case, you have to use the *.OTP file for programming, not the *.HEX file. After assemble, both OTP and HEX file are generated by automatically. The HEX file is used during program emulation on the emulator.

How to Program

To program the FLASH or MTP devices, user can use ABOV own programmer.

ABOV own programmer list

Manufacturer: ABOV Semiconductor Programmer:

**Choice-Sigma
StandAlone-Gang4
PGM-plus**

The Choice-Sigma is a ABOV Universal Single Programmer for

all of ABOV FLASH/OTP devices, also the StandAlone-Gang4 can program four FLASH/OTPs at once for ABOV device.

Ask to ABOV sales part for purchasing or more detail.

Programming Procedure

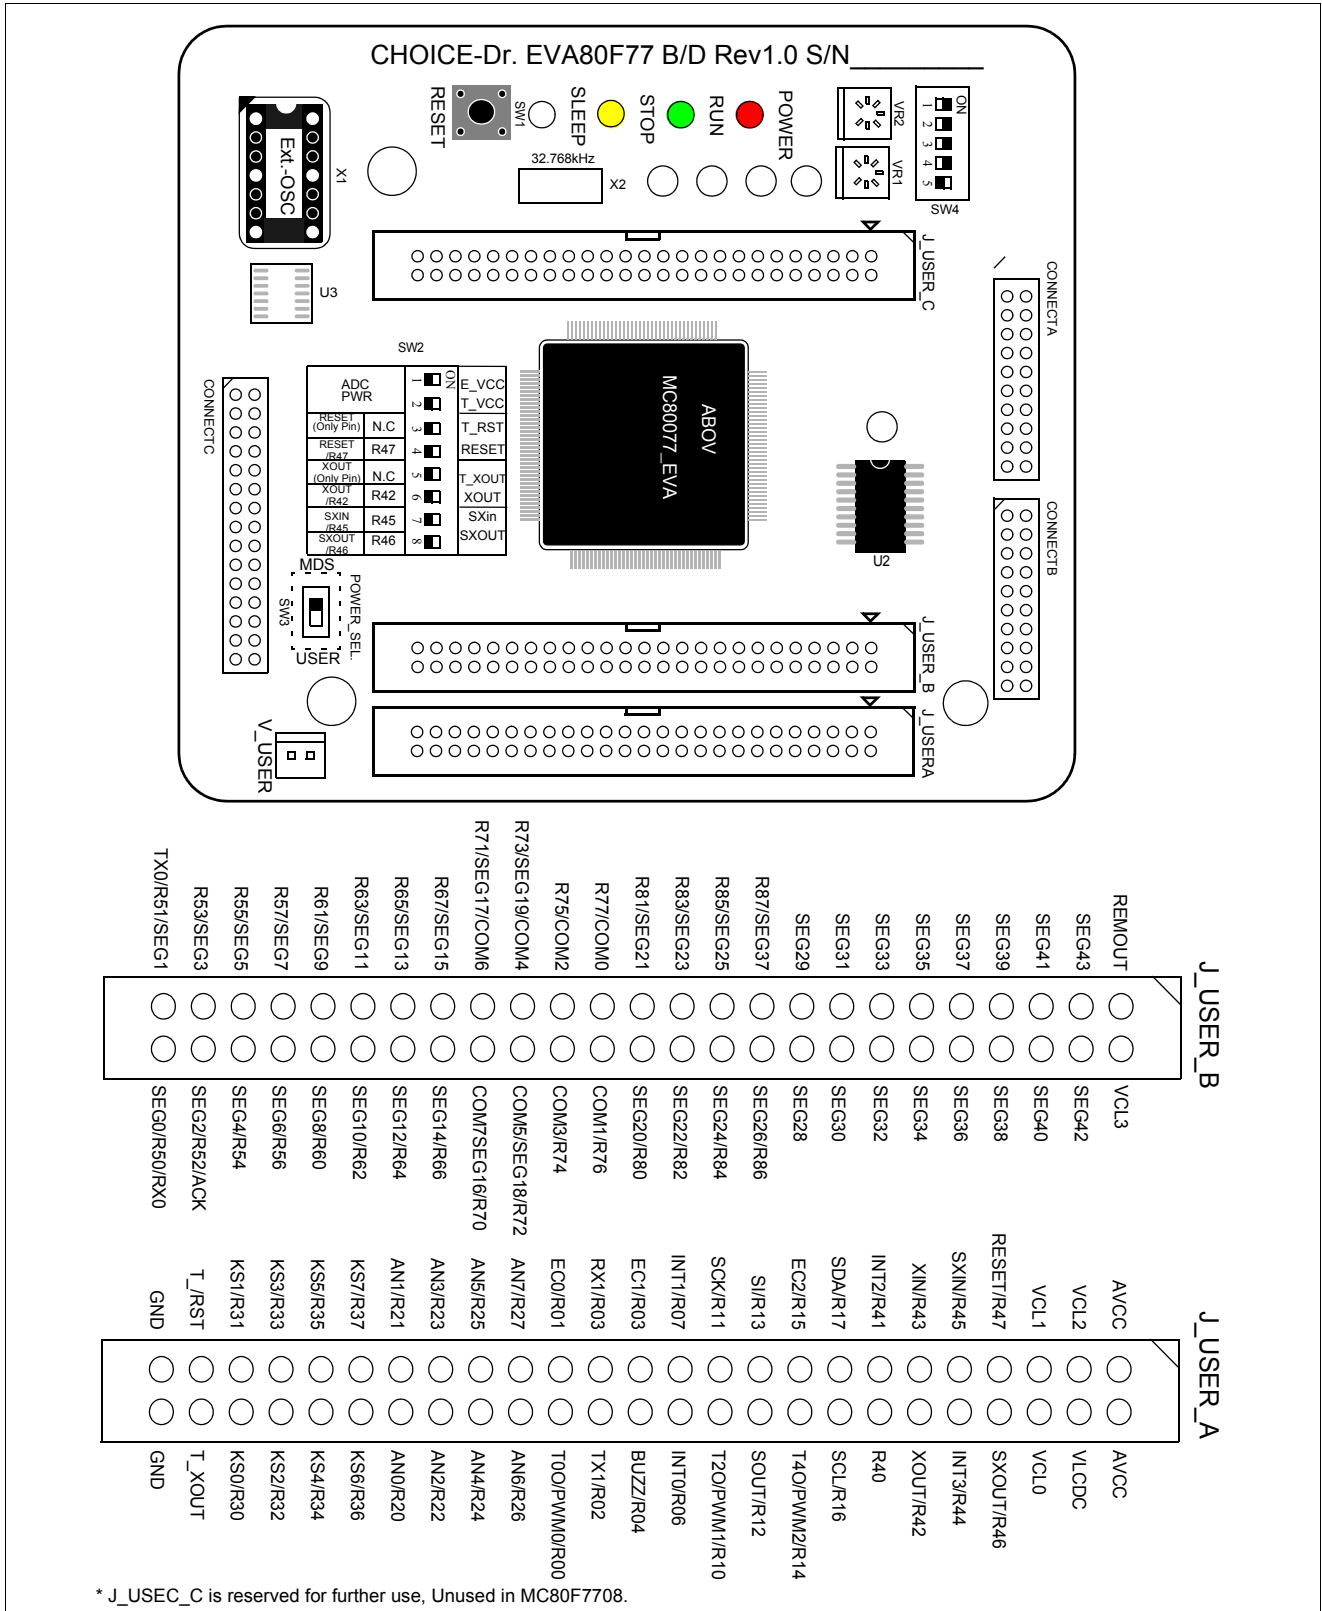

1. Select device MC80F7708.
2. Load the *.OTP file from the PC. The file is composed of Motorola-S1 format.

3. Set the programming address range as below table.

Address	Set Value
Buffer start address	E000 _H
Buffer end address	FFFF _H
Device start address	E000 _H

4. Mount the socket adapter on the programmer.
5. Start program/verify.

27. EMULATOR EVA. BOARD SETTING

28. IN-SYSTEM PROGRAMMING

28.1 Getting Started / Installation

The In-System Programming (ISP) is performed without removing the microcontroller from the system. The In-System Programming(ISP) facility consists of a series of internal hardware resources coupled with internal firm-ware through the serial port. The In-System Programming (ISP) facility has made in-circuit programming in an embedded application possible with a minimum of additional expense in components and circuit board area. The following section details the procedure for accomplishing the installation procedure.

1. Power off a target system.

2. Configure a target system as ISP mode.

Refer to “28.3 Hardware Conditions to Enter the ISP Mode”

3. Attach a ISP B/D into a target system.

4. Connect the serial (RS-232C) cable between a ISP board and available serial port of your PC.

5. Power on a target system.

6. Run the ABOV ISP software.

Download the ISP S/W from www.abov.co.kr.

Unzip the download file and run ISP_800.exe

7. Select a COM port and a device in the ISP S/W.

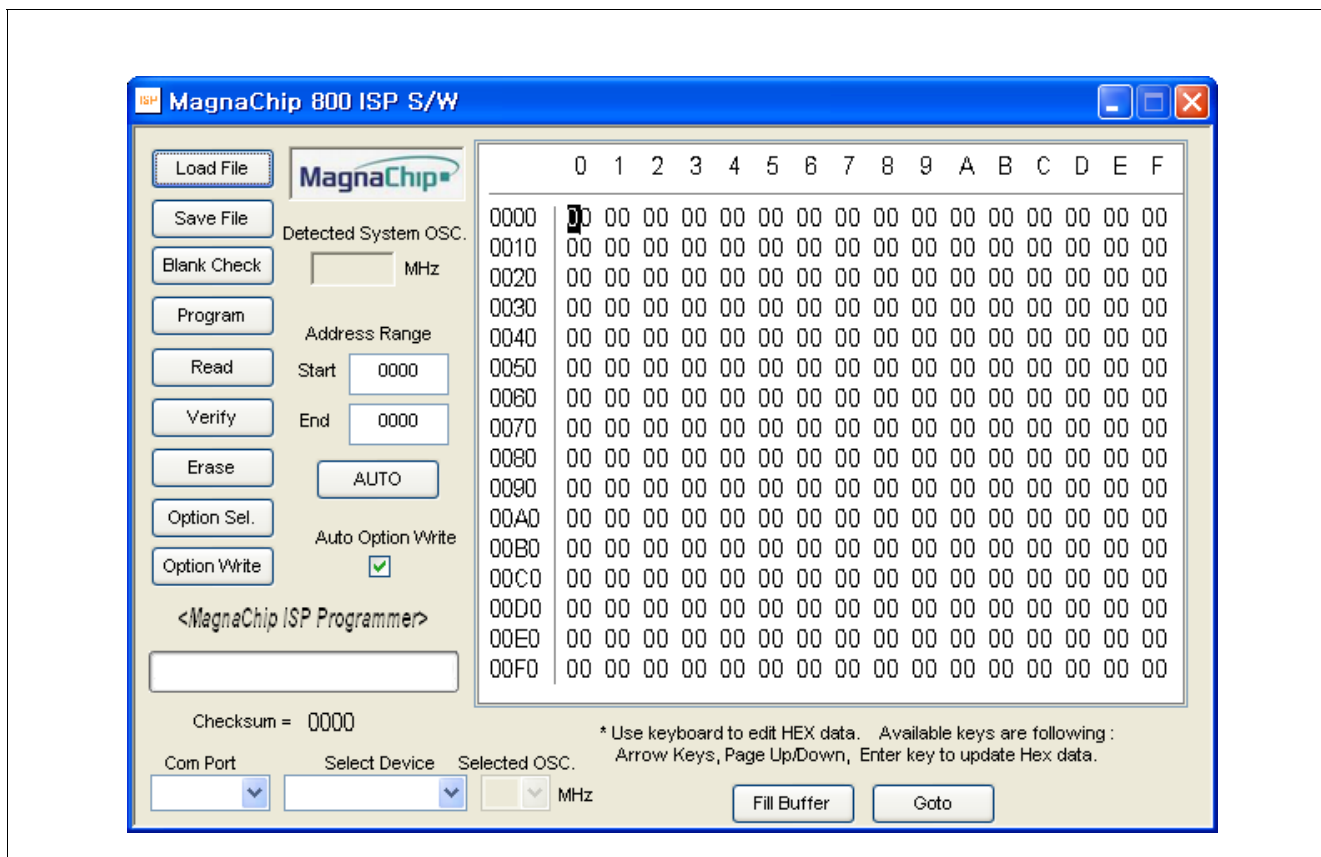

Figure 28-1 ISP software

28.2 Basic ISP S/W Information

The Figure 28-1 is the ISP software based on Windows™. This software is only supporting devices with UART. Main feature is automatically to search baudrates in range

Table 28-2. In case of not detecting its baudrates an user manually have to select specific baudrates.

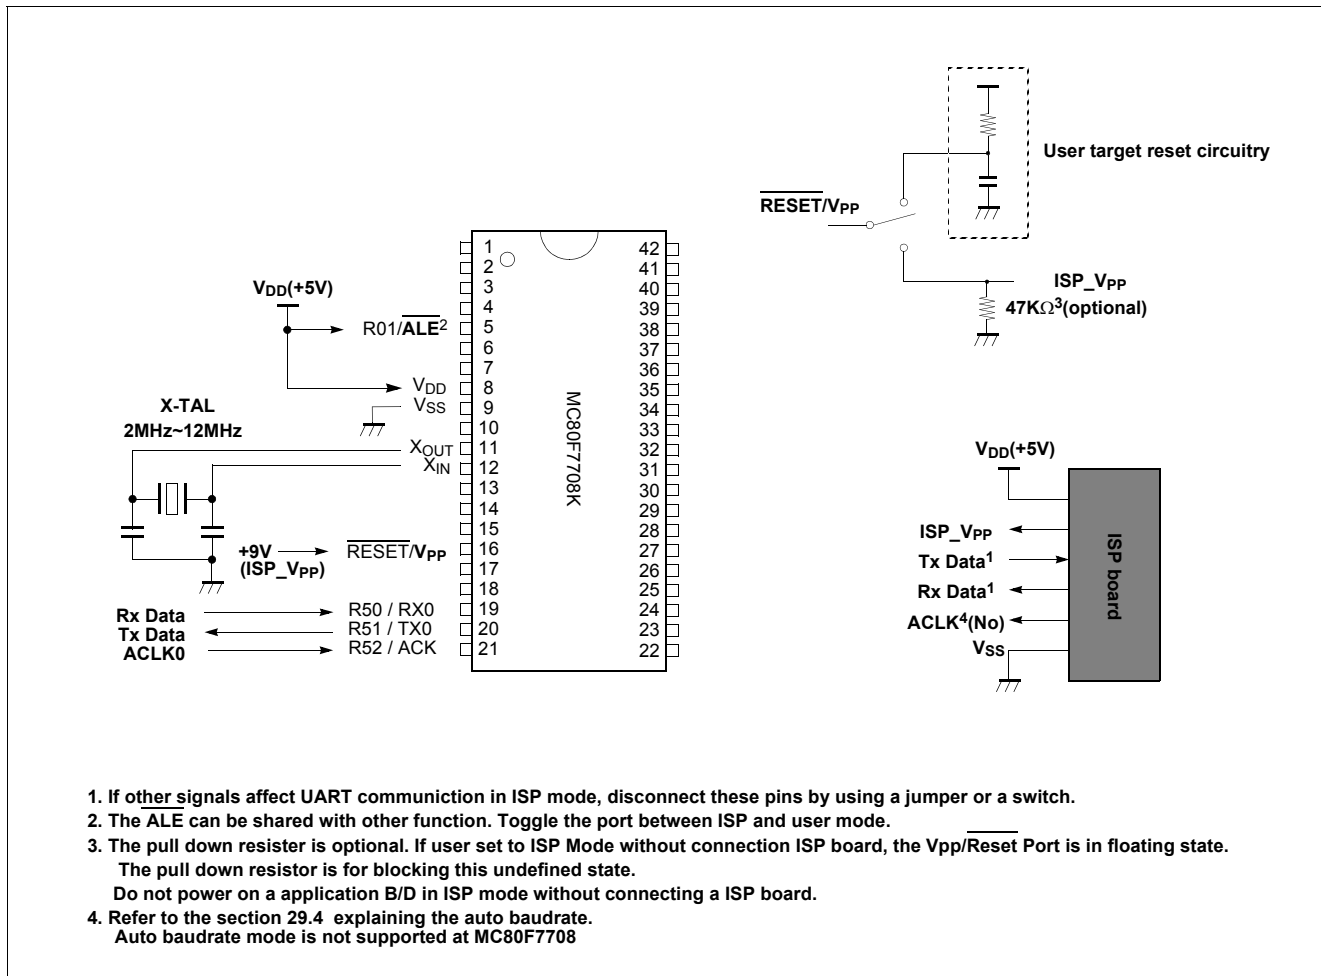

Function	Description
Load HEX File	Load the data from the selected file storage into the memory buffer.
Save HEX File	Save the current data in your memory buffer to a disk storage by using the Intel Motorola HEX format.
Blank Check	Verify whether or not a device is in an erased or unprogrammed state.
Program	This button enables you to place new data from the memory buffer into the target device.
Read	Read the data in the target MCU into the buffer for examination. The checksum will be displayed on the checksum box.
Verify	Assures that data in the device matches data in the memory buffer. If your device is secured, a verification error is detected.
Erase	Erase the data in your target MCU before programming it.
Option Selection	Set the configuration data of target MCU. The security locking is set with this button.
Option Write	Program the configuration data of target MCU. The security locking is performed with this button.
AUTO	Following sequence is performed ; 1.Erase 2.Program 3.Verify 4.Option Write
Edit Buffer	Modify the data in the selected address in your buffer memory
Fill Buffer	Fill the selected area with a data.
Goto	Display the selected page.
Detected System OSC.	Display user system clock which is detected in Auto baud rate mode.
Start _____	Starting address
End _____	End address
Checksum	Display the checksum(Hexdecimal) after reading the target device.
COM Port	Select a serial port.
Selected OSC.	Specify your target oscillator value with discarding below point in ACK mode only.
Select Device	Select target device.

Table 28-1 ISP Function Description

28.3 Hardware Conditions to Enter the ISP Mode

The boot loader can be executed by holding \overline{ALE} high, \overline{RESET}/V_{PP} as +9V, and $ACLK0$ (optional) with OSC.

1.8432MHz. The ISP function uses following pins: Tx/D0, Rx/D0, ALEB, ACLK and \overline{RESET}/V_{PP} .

1. If other signals affect UART communication in ISP mode, disconnect these pins by using a jumper or a switch.
2. The \overline{ALE} can be shared with other function. Toggle the port between ISP and user mode.
3. The pull down resistor is optional. If user set to ISP Mode without connection ISP board, the Vpp/Reset Port is in floating state. The pull down resistor is for blocking this undefined state. Do not power on a application B/D in ISP mode without connecting a ISP board.
4. Refer to the section 29.4 explaining the auto baudrate. Auto baudrate mode is not supported at MC80F7708

28.4 Sequence to enter ISP mode/user mode

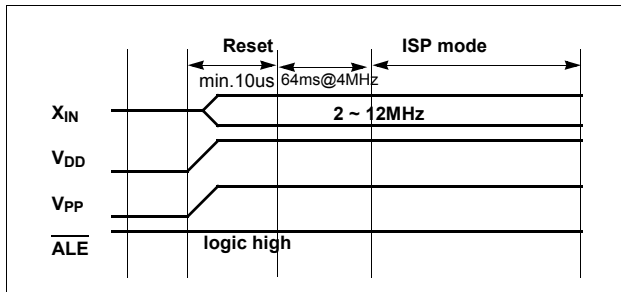

Figure 28-2 Timing diagram to enter the ISP mode

Sequence to enter ISP mode from user mode.

1. Power off a target system.
2. Configure a target system as ISP mode.
3. Attach a ISP B/D into a target system.
4. Run the ISP S/W and Select Device.
5. Power on a target system.

Sequence to enter user mode from ISP mode.

1. Close the ISP S/W.
2. Power off a target system.
3. Configure a target system as user mode
4. Detach a ISP B/D from a target system.
5. Power on.

28.5 Difference between auto baud rate and ACK mode

Auto Baud Rate Mode(No Use)

The ISP S/W detects user system clock and MCU configure a baud rate automatically. This mode does not need to connect the ACK pin of target MCU to ISP B/D. But the MC80F7708 does not support this mode.

ACK mode

If the ISP S/W can not detect user system clock, users have to enter a user system clock. This mode is only used when failed to detect user system clock automatically.

Note: Need to connect the ACK pin to ISP B/D.

The mode supported with devices is shown in Table 28-2 .

	Auto Baud Rate mode	ACK mode
MC80F0204	-	○
MC80F0224	○	○
MC80F0448	○	○
MC80F7708	-	○

Table 28-2 Supported modes according to devices

28.6 Reference ISP Circuit Diagram and ABOV Supplied ISP Board

The ISP software and hardware circuit diagram are provided at www.abov.co.kr.

To get a ISP B/D, contact to sales department. The following circuit diagram is for reference use.

Figure 28-3 Reference ISP Circuit Diagram

APPENDIX

A. INSTRUCTION

A.1 Terminology List

Terminology	Description
A	Accumulator
X	X - register
Y	Y - register
PSW	Program Status Word
#imm	8-bit Immediate data
dp	Direct Page Offset Address
!abs	Absolute Address
[]	Indirect expression
{}	Register Indirect expression
{ }+	Register Indirect expression, after that, Register auto-increment
.bit	Bit Position
A.bit	Bit Position of Accumulator
dp.bit	Bit Position of Direct Page Memory
M.bit	Bit Position of Memory Data (000H~0FFFH)
rel	Relative Addressing Data
upage	U-page (0FF00H~0FFFFH) Offset Address
n	Table CALL Number (0~15)
+	Addition
x	 Upper Nibble Expression in Opcode
y	 Upper Nibble Expression in Opcode
-	Subtraction
×	Multiplication
/	Division
()	Contents Expression
^	AND
∨	OR
⊕	Exclusive OR
~	NOT
←	Assignment / Transfer / Shift Left
→	Shift Right
↔	Exchange
=	Equal
≠	Not Equal
